

Title

reshape — Convert data from wide to long form and vice versa

Syntax

Basic syntax

```
reshape long stubnames , i(varlist) [options]
```

```
reshape wide stubnames , i(varlist) [options]
```

```
reshape long
```

```
reshape wide
```

```
reshape error
```

Advanced syntax

```
reshape i varlist
```

```
reshape j varname [values] [, string]
```

```
reshape xij fvarnames [, atw1(chars)]
```

```
reshape xi [varlist]
```

```
reshape [query]
```

```
reshape clear
```

options

description

* <i>i</i> (<i>varlist</i>)	use <i>varlist</i> as the ID variables
<i>j</i> (<i>varname</i> [<i>values</i>])	long→wide: <i>varname</i> , existing variable wide→long: <i>varname</i> , new variable optionally specify values to subset <i>varname</i>
<u>string</u>	<i>varname</i> is a string variable (default is numeric)

* *i*(*varlist*) is required.

where *values* is #[-#] [# ...] if *varname* is numeric (default)
 "string" ["string" ...] if *varname* is string

and where *stubnames* are variable names (long→wide), or stubs of variable names (wide→long), and either way, may contain @, denoting where *j* appears or is to appear in the name.

Menu

Data > Create or change data > Other variable-transformation commands > Convert data between wide and long

Description

`reshape` converts data from *wide* to *long* form and vice versa.

Options

`i(varlist)` specifies the variables whose unique values denote a logical observation. `i()` is required.

`j(varname [values])` specifies the variable whose unique values denote a subobservation. *values* lists the unique values to be used from *varname*, which typically are not explicitly stated because `reshape` will determine them automatically from the data.

`string` specifies that `j()` may contain string values.

`atwl(chars)`, available only with the advanced syntax and not shown in the dialog box, specifies that *chars* be substituted for the @ character when converting the data from wide to long form.

Remarks

Remarks are presented under the following headings:

- Description of basic syntax*
- Wide and long data forms*
- Avoiding and correcting mistakes*
- reshape long and reshape wide without arguments*
- Missing variables*
- Advanced issues with basic syntax: i()*
- Advanced issues with basic syntax: j()*
- Advanced issues with basic syntax: xij*
- Advanced issues with basic syntax: String identifiers for j()*
- Advanced issues with basic syntax: Second-level nesting*
- Description of advanced syntax*

Description of basic syntax

Before using `reshape`, you need to determine whether the data are in long or wide form. You also must determine the logical observation (`i`) and the subobservation (`j`) by which to organize the data. Suppose that you had the following data, which could be organized in wide or long form as follows:

(Continued on next page)

i X_{ij}				i	j	X_{ij}	
id	sex	inc80	inc81	inc82	id	year	sex	inc
1	0	5000	5500	6000	1	80	0	5000
2	1	2000	2200	3300	1	81	0	5500
3	0	3000	2000	1000	1	82	0	6000
					2	80	1	2000
					2	81	1	2200
					2	82	1	3300
					3	80	0	3000
					3	81	0	2000
					3	82	0	1000

Given these data, you could use `reshape` to convert from one form to the other:

```
. reshape long inc, i(id) j(year)          /* goes from left form to right */
. reshape wide inc, i(id) j(year)         /* goes from right form to left */
```

Because we did not specify `sex` in the command, Stata assumes that it is constant within the logical observation, here `id`.

Wide and long data forms

Think of the data as a collection of observations X_{ij} , where i is the logical observation, or group identifier, and j is the subobservation, or within-group identifier.

Wide-form data are organized by logical observation, storing all the data on a particular observation in one row. Long-form data are organized by subobservation, storing the data in multiple rows.

► Example 1

For example, we might have data on a person's ID, gender, and annual income over the years 1980–1982. We have two X_{ij} variables with the data in wide form:

```
. use http://www.stata-press.com/data/r11/reshape1
. list
```

	id	sex	inc80	inc81	inc82	ue80	ue81	ue82
1.	1	0	5000	5500	6000	0	1	0
2.	2	1	2000	2200	3300	1	0	0
3.	3	0	3000	2000	1000	0	0	1

To convert these data to the long form, we type

```
. reshape long inc ue, i(id) j(year)
(note: j = 80 81 82)

Data                wide  ->  long
-----
Number of obs.          3  ->   9
Number of variables     8  ->   5
j variable (3 values)   ->  year
xij variables:
      inc80 inc81 inc82 ->  inc
      ue80 ue81 ue82  ->  ue
```

There is no variable named `year` in our original, wide-form dataset. `year` will be a new variable in our long dataset. After this conversion, we have

```
. list, sep(3)
```

	id	year	sex	inc	ue
1.	1	80	0	5000	0
2.	1	81	0	5500	1
3.	1	82	0	6000	0
4.	2	80	1	2000	1
5.	2	81	1	2200	0
6.	2	82	1	3300	0
7.	3	80	0	3000	0
8.	3	81	0	2000	0
9.	3	82	0	1000	1

We can return to our original, wide-form dataset by using `reshape wide`.

```
. reshape wide inc ue, i(id) j(year)
(note: j = 80 81 82)
```

Data	long	->	wide
Number of obs.	9	->	3
Number of variables	5	->	8
j variable (3 values)	year	->	(dropped)
xij variables:			
	inc	->	inc80 inc81 inc82
	ue	->	ue80 ue81 ue82

```
. list
```

	id	inc80	ue80	inc81	ue81	inc82	ue82	sex
1.	1	5000	0	5500	1	6000	0	0
2.	2	2000	1	2200	0	3300	0	1
3.	3	3000	0	2000	0	1000	1	0

Converting from wide to long creates the `j (year)` variable. Converting back from long to wide drops the `j (year)` variable.

□ Technical note

If your data are in wide form and you do not have a group identifier variable (the `i(varlist)` required option), you can create one easily by using `generate`; see [D] **generate**. For instance, in the last example, if we did not have the `id` variable in our dataset, we could have created it by typing

```
. generate id = _n
```

Avoiding and correcting mistakes

reshape often detects when the data are not suitable for reshaping; an error is issued, and the data remain unchanged.

▷ Example 2

The following wide data contain a mistake:

```
. use http://www.stata-press.com/data/r11/reshape2, clear
. list
```

	id	sex	inc80	inc81	inc82
1.	1	0	5000	5500	6000
2.	2	1	2000	2200	3300
3.	3	0	3000	2000	1000
4.	2	0	2400	2500	2400

```
. reshape long inc, i(id) j(year)
(note: j = 80 81 82)
i=id does not uniquely identify the observations;
there are multiple observations with the same value of id.
Type "reshape error" for a listing of the problem observations.
r(9);
```

The *i* variable must be unique when the data are in the wide form; we typed *i*(*id*), yet we have 2 observations for which *id* is 2. (Is person 2 a male or female?) ◀

▷ Example 3

It is not a mistake when the *i* variable is repeated when the data are in long form, but the following data have a similar mistake:

```
. use http://www.stata-press.com/data/r11/reshapexp1
. list
```

	id	year	sex	inc
1.	1	80	0	5000
2.	1	81	0	5500
3.	1	81	0	5400
4.	1	82	0	6000

```
. reshape wide inc, i(id) j(year)
(note: j = 80 81 82)
year not unique within id;
there are multiple observations at the same year within id.
Type "reshape error" for a listing of the problem observations.
r(9);
```

In the long form, *i*(*id*) does not have to be unique, but *j*(*year*) must be unique within *i*; otherwise, what is the value of *inc* in 1981 for which *id*=1?

reshape told us to type `reshape error` to view the problem observations.

```
. reshape error
(note: j = 80 81 82)
i (id) indicates the top-level grouping such as subject id.
j (year) indicates the subgrouping such as time.
The data are in the long form; j should be unique within i.
There are multiple observations on the same year within id.
The following 2 of 4 observations have repeated year values:
```

	id	year
2.	1	81
3.	1	81

(data now sorted by id year)

◀

▶ Example 4

Consider some long-form data that have no mistakes. We list the first 4 observations.

```
. list in 1/4
```

	id	year	sex	inc	ue
1.	1	80	0	5000	0
2.	1	81	0	5500	1
3.	1	82	0	6000	0
4.	2	80	1	2000	1

Say that when converting the data to wide form, however, we forget to mention the `ue` variable (which varies within person).

```
. reshape wide inc, i(id) j(year)
(note: j = 80 81 82)
ue not constant within id
Type "reshape error" for a listing of the problem observations.
r(9);
```

Here `reshape` observed that `ue` was not constant within `i` and so could not restructure the data so that there were single observations on `i`. We should have typed

```
. reshape wide inc ue, i(id) j(year)
```

◀

In summary, there are three cases in which `reshape` will refuse to convert the data:

1. The data are in wide form and `i` is not unique.
2. The data are in long form and `j` is not unique within `i`.
3. The data are in long form and an unmentioned variable is not constant within `i`.

▶ Example 5

With some mistakes, `reshape` will probably convert the data and produce a surprising result. Suppose that we forget to mention that the `ue` variable varies within `id` in the following wide data:

```
. use http://www.stata-press.com/data/r11/reshape1
. list
```

	id	sex	inc80	inc81	inc82	ue80	ue81	ue82
1.	1	0	5000	5500	6000	0	1	0
2.	2	1	2000	2200	3300	1	0	0
3.	3	0	3000	2000	1000	0	0	1

```
. reshape long inc, i(id) j(year)
(note: j = 80 81 82)
```

```
Data
```

	wide	->	long
Number of obs.	3	->	9
Number of variables	8	->	7
j variable (3 values)		->	year
xij variables:	inc80 inc81 inc82	->	inc

```
. list, sep(3)
```

	id	year	sex	inc	ue80	ue81	ue82
1.	1	80	0	5000	0	1	0
2.	1	81	0	5500	0	1	0
3.	1	82	0	6000	0	1	0
4.	2	80	1	2000	1	0	0
5.	2	81	1	2200	1	0	0
6.	2	82	1	3300	1	0	0
7.	3	80	0	3000	0	0	1
8.	3	81	0	2000	0	0	1
9.	3	82	0	1000	0	0	1

We did not state that `ue` varied within `i`, so the variables `ue80`, `ue81`, and `ue82` were left as is. `reshape` did not complain. There is no real problem here because no information has been lost. In fact, this may actually be the result we wanted. Probably, however, we simply forgot to include `ue` among the X_{ij} variables.

If you obtain an unexpected result, here is how to undo it:

1. If you typed `reshape long ...` to produce the result, type `reshape wide` (without arguments) to undo it.
2. If you typed `reshape wide ...` to produce the result, type `reshape long` (without arguments) to undo it.

So, we can type

```
. reshape wide
```

to get back to our original, wide-form data and then type the `reshape long` command that we intended:

```
. reshape long inc ue, i(id) j(year)
```

◀

reshape long and reshape wide without arguments

Whenever you type a `reshape long` or `reshape wide` command with arguments, `reshape` remembers it. Thus you might type

```
. reshape long inc ue, i(id) j(year)
```

and work with the data like that. You could then type

```
. reshape wide
```

to convert the data back to the wide form. Then later you could type

```
. reshape long
```

to convert them back to the long form. If you save the data, you can even continue using `reshape wide` and `reshape long` without arguments during a future Stata session.

Be careful. If you create new X_{ij} variables, you must tell `reshape` about them by typing the full `reshape` command, although no real damage will be done if you forget. If you are converting from long to wide form, `reshape` will catch your error and refuse to make the conversion. If you are converting from wide to long, `reshape` will convert the data, but the result will be surprising: remember what happened when we forgot to mention the `ue` variable and ended up with `ue80`, `ue81`, and `ue82` in our long data; see *Example 5*. You can `reshape long` to undo the unwanted change and then try again.

Missing variables

When converting data from wide form to long form, `reshape` does not demand that all the variables exist. Missing variables are treated as variables with missing observations.

► Example 6

Let's drop `ue81` from the wide form of the data:

```
. use http://www.stata-press.com/data/r11/reshape1, clear
. drop ue81
. list
```

	id	sex	inc80	inc81	inc82	ue80	ue82
1.	1	0	5000	5500	6000	0	0
2.	2	1	2000	2200	3300	1	0
3.	3	0	3000	2000	1000	0	1

```
. reshape long inc ue, i(id) j(year)
(note: j = 80 81 82)
(note: ue81 not found)
```

Data	wide	->	long
Number of obs.	3	->	9
Number of variables	7	->	5
j variable (3 values)		->	year
xij variables:			
	inc80 inc81 inc82	->	inc
	ue80 ue81 ue82	->	ue

```
. list, sep(3)
```

	id	year	sex	inc	ue
1.	1	80	0	5000	0
2.	1	81	0	5500	.
3.	1	82	0	6000	0
4.	2	80	1	2000	1
5.	2	81	1	2200	.
6.	2	82	1	3300	0
7.	3	80	0	3000	0
8.	3	81	0	2000	.
9.	3	82	0	1000	1

`reshape` placed missing values where `ue81` values were unavailable. If we reshaped these data back to wide form by typing

```
. reshape wide inc ue, i(id) j(year)
```

the `ue81` variable would be created and would contain all missing values.

◀

Advanced issues with basic syntax: i()

The `i()` option can indicate one `i` variable (as our past examples have illustrated) or multiple variables. An example of multiple `i` variables would be hospital ID and patient ID within each hospital.

```
. reshape ... , i(hid pid)
```

Unique pairs of values for `hid` and `pid` in the data define the grouping variable for `reshape`.

Advanced issues with basic syntax: j()

The `j()` option takes a variable name (as our past examples have illustrated) or a variable name and a list of values. When the values are not provided, `reshape` deduces them from the data. Specifying the values with the `j()` option is rarely needed.

`reshape` never makes a mistake when the data are in long form and you type `reshape wide`. The values are easily obtained by tabulating the `j` variable.

`reshape` can make a mistake when the data are in wide form and you type `reshape long` if your variables are poorly named. Say that you have the `inc80`, `inc81`, and `inc82` variables, recording income in each of the indicated years, and you have a variable named `inc2`, which is not income but indicates when the area was reincorporated. You type

```
. reshape long inc, i(id) j(year)
```

`reshape` sees the `inc2`, `inc80`, `inc81`, and `inc82` variables and decides that there are four groups in which `j = 2, 80, 81, and 82`.

The easiest way to solve the problem is to rename the `inc2` variable to something other than “inc” followed by a number; see [D] **rename**.

You can also keep the name and specify the `j` values. To perform the reshape, you can type

```
. reshape long inc, i(id) j(year 80-82)
```

or

```
. reshape long inc, i(id) j(year 80 81 82)
```

You can mix the dash notation for value ranges with individual numbers. `reshape` would understand `80 82-87 89 91-95` as a valid values specification.

At the other extreme, you can omit the `j()` option altogether with `reshape long`. If you do, the `j` variable will be named `_j`.

Advanced issues with basic syntax: xij

When specifying variable names, you may include `@` characters to indicate where the numbers go.

► Example 7

Let's reshape the following data from wide to long form:

```
. use http://www.stata-press.com/data/r11/reshape3, clear
. list
```

	id	sex	inc80r	inc81r	inc82r	ue80	ue81	ue82
1.	1	0	5000	5500	6000	0	1	0
2.	2	1	2000	2200	3300	1	0	0
3.	3	0	3000	2000	1000	0	0	1

```
. reshape long inc@r ue, i(id) j(year)
(note: j = 80 81 82)
```

Data	wide	->	long
Number of obs.	3	->	9
Number of variables	8	->	5
j variable (3 values)		->	year
xij variables:			
	inc80r inc81r inc82r	->	incr
	ue80 ue81 ue82	->	ue

```
. list, sep(3)
```

	id	year	sex	incr	ue
1.	1	80	0	5000	0
2.	1	81	0	5500	1
3.	1	82	0	6000	0
4.	2	80	1	2000	1
5.	2	81	1	2200	0
6.	2	82	1	3300	0
7.	3	80	0	3000	0
8.	3	81	0	2000	0
9.	3	82	0	1000	1

At most one `@` character may appear in each name. If no `@` character appears, results are as if the `@` character appeared at the end of the name. So, the equivalent `reshape` command to the one above is

```
. reshape long inc@r ue@, i(id) j(year)
```

`inc@r` specifies variables named `inc#r` in the wide form and `incr` in the long form. The `@` notation may similarly be used for converting data from long to wide format:

```
. reshape wide inc@r ue, i(id) j(year)
```

◀

Advanced issues with basic syntax: String identifiers for `j()`

The `string` option allows `j` to take on string values.

▷ Example 8

Consider the following wide data on husbands and wives. In these data, `incm` is the income of the man and `incf` is the income of the woman.

```
. use http://www.stata-press.com/data/r11/reshape4, clear
. list
```

	id	kids	incm	incf
1.	1	0	5000	5500
2.	2	1	2000	2200
3.	3	2	3000	2000

These data can be reshaped into separate observations for males and females by typing

```
. reshape long inc, i(id) j(sex) string
(note: j = f m)
```

Data	wide	->	long
Number of obs.	3	->	6
Number of variables	4	->	4
j variable (2 values)		->	sex
xij variables:			
	incf incm	->	inc

The `string` option specifies that `j` take on nonnumeric values. The result is

```
. list, sep(2)
```

	id	sex	kids	inc
1.	1	f	0	5500
2.	1	m	0	5000
3.	2	f	1	2200
4.	2	m	1	2000
5.	3	f	2	2000
6.	3	m	2	3000

`sex` will be a string variable. Similarly, these data can be converted from long to wide form by typing

```
. reshape wide inc, i(id) j(sex) string
```

◀

Strings are not limited to being single characters or even having the same length. You can specify the location of the string identifier in the variable name by using the @ notation.

▷ Example 9

Suppose that our variables are named `id`, `kids`, `incmale`, and `incfem`.

```
. use http://www.stata-press.com/data/r11/reshapexp2, clear
. list
```

	id	kids	incmale	incfem
1.	1	0	5000	5500
2.	2	1	2000	2200
3.	3	2	3000	2000

```
. reshape long inc, i(id) j(sex) string
(note: j = fem male)
```

Data	wide	->	long
Number of obs.	3	->	6
Number of variables	4	->	4
j variable (2 values)		->	sex
xij variables:			
	incfem incmale	->	inc

```
. list, sep(2)
```

	id	sex	kids	inc
1.	1	fem	0	5500
2.	1	male	0	5000
3.	2	fem	1	2200
4.	2	male	1	2000
5.	3	fem	2	2000
6.	3	male	2	3000

If the wide data had variables named `minc` and `finc`, the appropriate `reshape` command would have been

```
. reshape long @inc, i(id) j(sex) string
```

The resulting variable in the long form would be named `inc`.

We can also place strings in the middle of the variable names. If the variables were named `incMome` and `incFome`, the `reshape` command would be

```
. reshape long inc@ome, i(id) j(sex) string
```

Be careful with string identifiers because it is easy to be surprised by the result. Say that we have wide data having variables named `incm`, `incf`, `uem`, `uef`, `agem`, and `agef`. To make the data long, we might type

```
. reshape long inc ue age, i(id) j(sex) string
```

Along with these variables, we also have the variable `agenda`. `reshape` will decide that the sexes are `m`, `f`, and `nda`. This would not happen without the `string` option if the variables were named `inc0`, `inc1`, `ue0`, `ue1`, `age0`, and `age1`, even with the `agenda` variable present in the data.

◀

Advanced issues with basic syntax: Second-level nesting

Sometimes the data may have more than one possible `j` variable for reshaping. Suppose that your data have both a year variable and a sex variable. One logical observation in the data might be represented in any of the following four forms:

```
. list in 1/4 // The long-long form
```

	hid	sex	year	inc
1.	1	f	90	3200
2.	1	f	91	4700
3.	1	m	90	4500
4.	1	m	91	4600

```
. list in 1/2 // The long-year wide-sex form
```

	hid	year	minc	finc
1.	1	90	4500	3200
2.	1	91	4600	4700

```
. list in 1/2 // The wide-year long-sex form
```

	hid	sex	inc90	inc91
1.	1	f	3200	4700
2.	1	m	4500	4600

```
. list in 1 // The wide-wide form
```

	hid	minc90	minc91	finc90	finc91
1.	1	4500	4600	3200	4700

`reshape` can convert any of these forms to any other. Converting data from the long–long form to the wide–wide form (or any of the other forms) takes two `reshape` commands. Here is how we would do it:

From		To		Command
year	sex	year	sex	
long	long	long	wide	<code>reshape wide @inc, i(hid year) j(sex) string</code>
long	wide	long	long	<code>reshape long @inc, i(hid year) j(sex) string</code>
long	long	wide	long	<code>reshape wide inc, i(hid sex) j(year)</code>
wide	long	long	long	<code>reshape long inc, i(hid sex) j(year)</code>
long	wide	wide	wide	<code>reshape wide minc finc, i(hid) j(year)</code>
wide	wide	long	wide	<code>reshape long minc finc, i(hid) j(year)</code>
wide	long	wide	wide	<code>reshape wide @inc90 @inc91, i(hid) j(sex) string</code>
wide	wide	wide	long	<code>reshape long @inc90 @inc91, i(hid) j(sex) string</code>

Description of advanced syntax

The advanced syntax is simply a different way of specifying the `reshape` command, and it has one seldom-used feature that provides extra control. Rather than typing one `reshape` command to describe the data and perform the conversion, such as

```
. reshape long inc, i(id) j(year)
```

you type a sequence of `reshape` commands. The initial commands describe the data, and the last command performs the conversion:

```
. reshape i id
. reshape j year
. reshape xij inc
. reshape long
```

`reshape i` corresponds to `i()` in the basic syntax.

`reshape j` corresponds to `j()` in the basic syntax.

`reshape xij` corresponds to the variables specified in the basic syntax. `reshape xij` also accepts the `atw1()` option for use when `@` characters are specified in the *fvarnames*. `atw1` stands for at-when-long. When you specify names such as `inc@r` or `ue@`, in the long form the names become `incr` and `ue`, and the `@` character is ignored. `atw1()` allows you to change `@` into whatever you specify. For example, if you specify `atw1(X)`, the long-form names become `incXr` and `ueX`.

There is also one more specification, which has no counterpart in the basic syntax:

```
. reshape xi varlist
```

In the basic syntax, Stata assumes that all unspecified variables are constant within `i`. The advanced syntax works the same way, unless you specify the `reshape xi` command, which names the constant-within-`i` variables. If you specify `reshape xi`, any variables that you do not explicitly specify are dropped from the data during the conversion.

As a practical matter, you should explicitly drop the unwanted variables before conversion. For instance, suppose that the data have variables `inc80`, `inc81`, `inc82`, `sex`, `age`, and `age2` and that you no longer want the `age2` variable. You could specify

```
. reshape xi sex age
```

or

```
. drop age2
```

and leave `reshape xi` unspecified.

`reshape xi` does have one minor advantage. It saves `reshape` the work of determining which variables are unspecified. This saves a relatively small amount of computer time.

Another advanced-syntax feature is `reshape query`, which is equivalent to typing `reshape` by itself. `reshape query` reports which `reshape` parameters have been defined. `reshape i`, `reshape j`, `reshape xij`, and `reshape xi` specifications may be given in any order and may be repeated to change or correct what has been specified.

Finally, `reshape clear` clears the definitions. `reshape` definitions are stored with the dataset when you save it. `reshape clear` allows you to erase these definitions.

The basic syntax of `reshape` is implemented in terms of the advanced syntax, so you can mix basic and advanced syntaxes.

Saved results

reshape stores the following characteristics with the data (see [P] **char**):

<code>._dta[ReS_i]</code>	i variable names
<code>._dta[ReS_j]</code>	j variable name
<code>._dta[ReS_jv]</code>	j values, if specified
<code>._dta[ReS_Xij]</code>	X_{ij} variable names
<code>._dta[ReS_Xi]</code>	X_i variable names, if specified
<code>._dta[ReS_atw1]</code>	atw1() value, if specified
<code>._dta[ReS_str]</code>	1 if option string specified; 0 otherwise

Methods and formulas

reshape is implemented as an ado-file.

Acknowledgment

This version of reshape was based in part on the work of Jeroen Weesie (1997), Utrecht University, The Netherlands.
