## Contents

${ }^{+}$This manual includes features that are part of StataNow.
Intro Introduction to base reference manual ..... 1
about Display information about your Stata ..... 8
ado update Update community-contributed packages ..... 9
ameans Arithmetic, geometric, and harmonic means ..... 13
anova Analysis of variance and covariance ..... 17
anova postestimation Postestimation tools for anova ..... 59
areg Linear regression with many indicator variables ${ }^{+}$ ..... 76
areg postestimation Postestimation tools for areg ..... 86
betareg Beta regression ..... 91
betareg postestimation Postestimation tools for betareg ..... 101
binreg Generalized linear models: Extensions to the binomial family ..... 105
binreg postestimation Postestimation tools for binreg ..... 118
biprobit Bivariate probit regression ..... 122
biprobit postestimation Postestimation tools for biprobit ..... 130
bitest Binomial probability test ..... 134
bootstrap Bootstrap sampling and estimation ..... 139
bootstrap postestimation Postestimation tools for bootstrap ..... 162
boxcox Box-Cox regression models ..... 166
boxcox postestimation Postestimation tools for boxcox ..... 177
brier Brier score decomposition ..... 182
bsample Sampling with replacement ..... 189
bstat Report bootstrap results ..... 198
centile Report centile and confidence interval ..... 206
churdle Cragg hurdle regression ..... 213
churdle postestimation Postestimation tools for churdle ..... 224
ci Confidence intervals for means, proportions, and variances ..... 230
clogit Conditional (fixed-effects) logistic regression ..... 249
clogit postestimation Postestimation tools for clogit ..... 266
cloglog Complementary log-log regression ..... 272
cloglog postestimation Postestimation tools for cloglog ..... 282
cls Clear Results window ..... 286
cnsreg Constrained linear regression ..... 287
cnsreg postestimation Postestimation tools for cnsreg ..... 293
constraint Define and list constraints ..... 297
contrast Contrasts and linear hypothesis tests after estimation ..... 301
contrast postestimation Postestimation tools for contrast ..... 368
copyright Display copyright information ..... 370
Copyright Apache Apache copyright notification ..... 371

correlate Correlations of variables ..... 410
cpoisson Censored Poisson regression ..... 420
cpoisson postestimation Postestimation tools for cpoisson ..... 427
cumul Cumulative distribution ..... 433
cusum Cusum plots and tests for binary variables ..... 438
dbLaunch dialog443
demandsys Estimation of flexible demand systems ..... 445
demandsys postestimation Postestimation tools for demandsys ..... 489
Diagnostic plots Distributional diagnostic plots ..... 505
display Substitute for a hand calculator ..... 520
do Execute commands from a file ..... 522
doedit Edit do-files and other text files ..... 524
dotplot Comparative distribution dotplots ..... 526
dstdize Direct and indirect standardization ..... 534
dtable Create a table of descriptive statistics ..... 554
dydx Calculate numeric derivatives and integrals ..... 585
eform_option Displaying exponentiated coefficients ..... 592
eivreg Errors-in-variables regression ..... 594
eivreg postestimation Postestimation tools for eivreg ..... 601
Epitab Tables for epidemiologists ..... 604
Error messages Error messages and return codes ..... 669
esize Effect size based on mean comparison ..... 670
estat Postestimation statistics ..... 683
estat classification Classification statistics and table ..... 684
estat gof Pearson or Hosmer-Lemeshow goodness-of-fit test ..... 688
estat ic Display information criteria ..... 698
estat summarize Summarize estimation sample ..... 706
estat vce Display covariance matrix estimates ..... 710
estimates Save and manipulate estimation results ..... 714
estimates describe Describe estimation results ..... 718
estimates for Repeat postestimation command across models ..... 721
estimates notes Add notes to estimation results ..... 723
estimates replay Redisplay estimation results ..... 726
estimates save Save and use estimation results ..... 729
estimates selected Show selected coefficients ..... 733
estimates stats Model-selection statistics ..... 737
estimates store Store and restore estimation results ..... 741
estimates table Compare estimation results ..... 744
estimates title Set title for estimation results ..... 752
Estimation options Estimation options ..... 753
etable Create a table of estimation results ..... 757
exit Exit Stata ..... 780
exlogistic Exact logistic regression ..... 781
exlogistic postestimation Postestimation tools for exlogistic ..... 799
expoisson Exact Poisson regression ..... 804
expoisson postestimation Postestimation tools for expoisson ..... 818
fp Fractional polynomial regression ..... 820
fp postestimation Postestimation tools for fp ..... 844
fracreg Fractional response regression ..... 853
fracreg postestimation Postestimation tools for fracreg ..... 863
frontier Stochastic frontier models ..... 871
frontier postestimation Postestimation tools for frontier ..... 887
fvrevar Factor-variables operator programming command ..... 892
fvset Declare factor-variable settings ..... 896
gllamm Generalized linear and latent mixed models ..... 902
glm Generalized linear models ..... 904
glm postestimation Postestimation tools for glm ..... 939
gmm Generalized method of moments estimation ..... 946
gmm postestimation Postestimation tools for gmm 1017
grmeanbyGraph means and medians by categorical variables 1023
hausman Hausman specification test 1026
heckman Heckman selection model 1036
heckman postestimation Postestimation tools for heckman 1053
heckoprobit Ordered probit model with sample selection 1060
heckoprobit postestimation Postestimation tools for heckoprobit 1069
heckpoisson Poisson regression with sample selection 1075
heckpoisson postestimation Postestimation tools for heckpoisson 1085
heckprobit Probit model with sample selection 1091
heckprobit postestimation Postestimation tools for heckprobit 1100
help

sureg Zellner's seemingly unrelated regression 2888
sureg postestimation Postestimation tools for sureg 2897
swilk Shapiro-Wilk and Shapiro-Francia tests for normality 2901
symmetry Symmetry and marginal homogeneity tests 2907
table intro Introduction to tables of frequencies, summaries, and command results 2916
table oneway One-way tabulation 2921
table twoway Two-way tabulation 2929
table multiway Multiway tables 2939
table summary Table of summary statistics 2953
table hypothesis tests Table of hypothesis tests ..... 2966
table regression Table of regression results ..... 2976
table Table of frequencies, summaries, and command results ..... 2988
tabstat Compact table of summary statistics 3005
tabulate oneway One-way table of frequencies 3011
tabulate twoway Two-way table of frequencies 3020
tabulate, summarize() One- and two-way tables of summary statistics 3038
test Test linear hypotheses after estimation 3043
testnl Test nonlinear hypotheses after estimation 3065
tetrachoric ..... Tetrachoric correlations for binary variables 3075
tnbreg Truncated negative binomial regression 3086
tnbreg postestimation Postestimation tools for tnbreg 3095
tobitTobit regression 3100
tobit postestimation Postestimation tools for tobit 3109total
total postestimationEstimate totals3114
tpoisson Truncated Poisson regression ..... 3122
tpoisson postestimation Postestimation tools for tpoisson 3130
translate Print and translate logs 3136
truncreg Truncated regression 3148
truncreg postestimation Postestimation tools for truncreg 3155
ttest $t$ tests (mean-comparison tests) 3159
update Check for official updates 3171
vce_option Variance estimators 3174
view View files and logs 3179
vwls Variance-weighted least squares 3182
vwls postestimation Postestimation tools for vwls 3189
which Display location of an ado-file 3192
wildbootstrap Wild cluster bootstrap inference 3194
xi Interaction expansion 3208
zinb Zero-inflated negative binomial regression 3219
zinb postestimation Postestimation tools for zinb 3228
ziologit Zero-inflated ordered logit regression 3233
ziologit postestimation Postestimation tools for ziologit 3242
zioprobitZero-inflated ordered probit regression 3248
zioprobit postestimation Postestimation tools for zioprobit 3257
zip Zero-inflated Poisson regression 3264
zip postestimation Postestimation tools for zip 3272
ztest $z$ tests (mean-comparison tests, known variance) ..... 3278
Subject and author index ..... 3293

## Cross-referencing the documentation

When reading this manual, you will find references to other Stata manuals, for example, [U] 27 Overview of Stata estimation commands; [R] regress; and [D] reshape. The first example is a reference to chapter 27, Overview of Stata estimation commands, in the User's Guide; the second is a reference to the regress entry in the Base Reference Manual; and the third is a reference to the reshape entry in the Data Management Reference Manual.

All the manuals in the Stata Documentation have a shorthand notation:

| [GSM] | Getting Started with Stata for Mac |
| :--- | :--- |
| [GSU] | Getting Started with Stata for Unix |
| [GSW] | Getting Started with Stata for Windows |
| [U] | Stata User's Guide |
| [R] | Stata Base Reference Manual |
| [ADAPT] | Stata Adaptive Designs: Group Sequential Trials Reference Manual |
| [BAYES] | Stata Bayesian Analysis Reference Manual |
| [BMA] | Stata Bayesian Model Averaging Reference Manual |
| [CAUSAL] | Stata Causal Inference and Treatment-Effects Estimation Reference Manual |
| [CM] | Stata Choice Models Reference Manual |
| [D] | Stata Data Management Reference Manual |
| [DSGE] | Stata Dynamic Stochastic General Equilibrium Models Reference Manual |
| [ERM] | Stata Extended Regression Models Reference Manual |
| [FMM] | Stata Finite Mixture Models Reference Manual |
| [FN] | Stata Functions Reference Manual |
| [G] | Stata Graphics Reference Manual |
| [IRT] | Stata Item Response Theory Reference Manual |

## Title

Intro - Introduction to base reference manual

Description Remarks and examples Also see

## Description

This entry describes the organization of the reference manuals.

## Remarks and examples

The complete list of reference manuals is as follows:
[R] Stata Base Reference Manual
[ADAPT] Stata Adaptive Designs: Group Sequential Trials Reference Manual
[BAYES] Stata Bayesian Analysis Reference Manual
[BMA] Stata Bayesian Model Averaging Reference Manual
[CAUSAL] Stata Causal Inference and Treatment-Effects Estimation Reference Manual
[CM] Stata Choice Models Reference Manual
[D] Stata Data Management Reference Manual
[DSGE] Stata Dynamic Stochastic General Equilibrium Models Reference Manual
[ERM] Stata Extended Regression Models Reference Manual
[FMM] Stata Finite Mixture Models Reference Manual
[FN] Stata Functions Reference Manual
[G] Stata Graphics Reference Manual
[IRT] Stata Item Response Theory Reference Manual
[LASSO] Stata Lasso Reference Manual
[XT] Stata Longitudinal-Data/Panel-Data Reference Manual
[META] Stata Meta-Analysis Reference Manual
[ME] Stata Multilevel Mixed-Effects Reference Manual
[MI] Stata Multiple-Imputation Reference Manual
[MV] Stata Multivariate Statistics Reference Manual
[PSS] Stata Power, Precision, and Sample-Size Reference Manual
[P] Stata Programming Reference Manual
[RPT] Stata Reporting Reference Manual
[SP] Stata Spatial Autoregressive Models Reference Manual
[SEM] Stata Structural Equation Modeling Reference Manual
[SVY] Stata Survey Data Reference Manual
[ST] Stata Survival Analysis Reference Manual
[TABLES] Stata Customizable Tables and Collected Results Reference Manual
[TS] Stata Time-Series Reference Manual
[M] Mata Reference Manual

When we refer to "reference manuals", we mean all manuals listed above.
When we refer to the specialty manuals, we mean all the manuals listed above except [R].

## Arrangement of the reference manuals

Each manual contains the following sections:

- Contents.

A table of contents can be found at the beginning of each manual.

- Cross-referencing the documentation.

This entry lists all the manuals and explains how they are cross-referenced.

- Introduction.

This entry-usually called intro-provides an overview of the manual. In the specialty manuals, this introduction suggests entries that you might want to read first and provides information about new features.

Each specialty manual contains an overview of the commands described in it.

- Entries.

Entries are arranged in alphabetical order. Most entries describe Stata commands, but some entries discuss concepts, and others provide overviews.
Entries that describe estimation commands are followed by an entry discussing postestimation commands that are available for use after the estimation command. For example, the xtlogit entry in the [XT] manual is followed by the xtlogit postestimation entry.

- Glossary.

A glossary is contained in all the specialty manuals.
To find information and commands quickly, use Stata's search command; see $[R]$ search (see the entry search in the [R] manual).

Each reference manual does not contain its own author or subject index. A combined author index and a combined subject index for all reference manuals can be found in the Stata Index, [I]. This manual also contains a combined subject table of contents for all reference manuals and the User's Guide, an acronym glossary, and a vignette index.

## Arrangement of each entry

Entries in most of the Stata reference manuals contain the following sections, which are explained below:

Description<br>Quick start<br>Menu<br>Syntax<br>Options<br>Remarks and examples<br>Stored results<br>Methods and formulas<br>Acknowledgments<br>References<br>Also see

## Description

The purpose of the command is briefly described here.

## Quick start

A quick start lists common uses of the command and the corresponding syntax for each.
For details on the syntax elements shown in the Quick start examples and to further customize the examples shown, see the Syntax and Options sections of the entry.

If you prefer to use the GUI, see the Menu section of the entry.
For applied examples of the syntax, see Remarks and examples.

## Menu

A menu indicates how the dialog box for the command may be accessed using the menu system.

## Syntax

A command's syntax diagram shows how to type the command, indicates all possible options, and gives the minimal allowed abbreviations for all the items in the command. For instance, the syntax diagram for the summarize command is
summarize $[$ varlist $][$ if $][$ in $][$ weight $][$, options $]$
options
Main
detail
meanonly
format
separator(\#)
display_options

Description
display additional statistics
suppress the display; calculate only the mean; programmer's option use variable's display format draw separator line after every \# variables; default is separator (5) control spacing and base and empty cells
varlist may contain factor variables; see [U] 11.4.3 Factor variables.
varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.
by, collect, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.
aweights, fweights, and iweights are allowed. However, iweights may not be used with the detail option; see
[U] 11.1.6 weight.
Items in the typewriter-style font should be typed exactly as they appear in the diagram, although they may be abbreviated. Underlining indicates the shortest abbreviations where abbreviations are allowed. For instance, summarize may be abbreviated su, sum, summ, etc., or it may be spelled out completely. Items in the typewriter font that are not underlined may not be abbreviated.

Square brackets denote optional items. In the syntax diagram above, varlist, if, in, weight, and the options are optional.

The options are listed in a table immediately following the diagram, along with a brief description of each.

Items typed in italics represent arguments for which you are to substitute variable names, observation numbers, and the like.

The diagrams use the following symbols:
\# Indicates a literal number, for example, 5; see [U] 12.2 Numbers.
[ ] Anything enclosed in brackets is optional.
$\} \quad$ At least one of the items enclosed in braces must appear.
| The vertical bar separates alternatives.
$\%$ fmt Any Stata format, for example, \%8.2f; see [U] 12.5 Formats: Controlling how data are displayed.
depvar The dependent variable in an estimation command; see [U] 20 Estimation and postestimation commands.
$\exp \quad$ Any algebraic expression, for example, (5+myvar)/2; see [U] 13 Functions and expressions.
filename Any filename; see [U] 11.6 Filenaming conventions.
indepvars The independent variables in an estimation command; see [U] 20 Estimation and postestimation commands.
newvar A variable that will be created by the current command; see [U] 11.4.2 Lists of new variables.
numlist A list of numbers; see [U] 11.1.8 numlist.
oldvar A previously created variable; see [U] 11.4.1 Lists of existing variables.
options A list of options; see [U] 11.1.7 options.
range An observation range, for example, 5/20; see [U] 11.1.4 in range.
"string" Any string of characters enclosed in double quotes; see [U] 12.4 Strings.
varlist A list of variable names; see [U] 11.4 varname and varlists. If varlist allows factor variables, a note to that effect will be shown below the syntax diagram; see [U] 11.4.3 Factor variables. If varlist allows time-series operators, a note to that effect will be shown below the syntax diagram; see [U] 11.4.4 Time-series varlists.
varname A variable name; see [U] 11.3 Naming conventions.
weight A [wgttype=exp] modifier; see [U] 11.1.6 weight and [U] 20.24 Weighted estimation.
xvar The variable to be displayed on the horizontal axis.
$y v a r \quad$ The variable to be displayed on the vertical axis.
The Syntax section will indicate whether factor variables or time-series operators may be used with a command. summarize allows factor variables and time-series operators.

If a command allows prefix commands, this will be indicated immediately following the table of options. summarize allows by.

If a command allows weights, the types of weights allowed will be specified, with the default weight listed first. summarize allows aweights, fweights, and iweights, and if the type of weight is not specified, the default is aweights.

## Options

If the command allows any options, they are explained here, and for dialog users the location of the options in the dialog is indicated. For instance, in the logistic entry in this manual, the Options section looks like this:
$\qquad$ Model

Maximization

## Remarks and examples

The explanations under Description and Options are exceedingly brief and technical; they are designed to provide a quick summary. The remarks explain in English what the preceding technical jargon means. Examples are used to illustrate the command.

Links to video examples posted on Stata's YouTube channel are provided at the end of this section.

## Stored results

Commands are classified as e-class, r-class, s-class, or n-class, according to whether they store calculated results in $e(), r(), s()$, or not at all. These results can then be used in subroutines by other programs (ado-files). Such stored results are documented here; see [U] 18.8 Accessing results calculated by other programs and [U] 18.9 Accessing results calculated by estimation commands.

## Methods and formulas

The techniques and formulas used in obtaining the results are described here as tersely and technically as possible.

## Acknowledgments

Some Stata commands began as community-contributed commands, or they were enhanced after suggestions by a Stata user. Here we acknowledge these contributions.

## References

Published sources are listed that either were directly referenced in the preceding text or might be of interest.

## Also see <br> Other manual entries relating to this entry are listed that might also interest you.

Elizabeth L. ("Betty") Scott (1917-1988) was an astronomer and mathematician trained at the University of California at Berkeley. She published her first paper when she was just 22 years old, and her work was focused on comets for much of her early academic career.

During World War II, Scott began working at the statistical laboratory at Berkeley, which had recently been established by Jerzy Neyman, sparking what would be a long and fruitful collaboration with him. After the war, she shifted her focus toward mathematics and statistics, partly because of limited career opportunities as an astronomer, though she still applied her research to astronomical topics. For example, in 1949 she published a paper using statistical techniques to analyze the distribution of binary star systems. She also published papers examining the distribution of galaxies, and she is the name behind the "Scott effect", which helps determine the distances to galaxies. Later in her career, Scott applied her statistical knowledge to problems associated with ozone depletion and its effects on the incidence of skin cancer as well as weather modification. She was also a champion of equality for women graduate students and faculty.
Among Scott's many awards and accomplishments, she was elected an honorary fellow of the Royal Statistical Society and was a fellow of the American Association for the Advancement of Science. In 1992, the Committee of Presidents of Statistical Societies established the Elizabeth L. Scott Award, a biannual award to recognize those who have strived to enhance the status of women within the statistics profession.

Janet Lippe Norwood (1923-2015) was born in Newark, New Jersey. She obtained her PhD from Tufts University and taught political science at Wellesley College. Norwood made significant contributions while she was the first female commissioner for the Bureau of Labor Statistics (BLS). She accomplished the goal of conducting the Consumer Expenditure Survey annually, a long-time goal of the BLS, and saved the National Longitudinal Survey from termination. As commissioner, she would present data on national unemployment before the Joint Economic Committee on a monthly basis, a duty that she performed with unwavering impartiality. Under her direction, the statistical quality of reported indicators improved, as did the cooperation of the BLS with the Census Bureau and the National Center for Health Statistics.

After her role as commissioner, she was the Chair of the Advisory Council on Unemployment Compensation, appointed by presidents George H. W. Bush and Bill Clinton. She also held a variety of other leadership positions, including president of the American Statistical Association, board member of the American Economic Association, and chair of a statistical committee for the OECD. Norwood was a trailblazer. In her honor, the University of Alabama at Birmingham created the Janet L. Norwood Award to recognize women in statistics.

## Title

ado update - Update community-contributed packages

| Description | Quick start | Syntax | Options |
| :--- | :--- | :--- | :--- |
| Remarks and examples | Stored results | Also see |  |

## Description

ado update checks for available updates to community-contributed packages. To update packages, use ado update, update. By default, only packages in the PLUS directory are checked.

## Quick start

List available updates for community-contributed packages
ado update
Install updates for community-contributed packages
ado update, update
Install updates from Statistical Software Components (SSC) Archive only ado update, update ssconly

## Syntax

ado update $[$ pkglist $][$, options $]$

| options | Description |
| :--- | :--- |
| update | perform update; default is to list packages that have updates, but not to <br> update them |
| all | include packages that might have updates; default is to list or update <br> only packages that are known to have updates <br> check only packages obtained from SSC Archive; default is to check all installed <br> packages |
| ssconly | dir $($ dir $)$ <br> verbose packages installed in dir; default is to check those installed in PLUS <br> provide output to assist in debugging network problems |

## Options

update specifies that packages with updates be updated. The default is simply to list the packages that could be updated without actually performing the update.

The first time you ado update, do not specify this option. Once you see ado update work, you will be more comfortable with it. Then type

```
. ado update, update
```

The packages that can be updated will be listed and updated.
all is rarely specified. Sometimes, ado update cannot determine whether a package you previously installed has been updated. ado update can determine that the package is still available over the web but is unsure whether the package has changed. Usually, the package has not changed, but if you want to be certain that you are using the latest version, reinstall from the source.
Specifying all does this. Typing
. ado update, all
adds such packages to the displayed list as needing updating but does not update them. Typing
. ado update, update all
lists such packages and updates them.
ssconly specifies that ado update check only packages obtained from the Statistical Software Components (SSC) Archive at Boston College, which is provided at http://repec.org. See [R] ssc for more information on the SSC Archive.
$\operatorname{dir}(d i r)$ specifies which installed packages be checked. The default is $\operatorname{dir}$ (PLUS), and that is probably correct. If you are responsible for maintaining a large system, however, you may have previously installed packages in dir (SITE), where they are shared across users. See [P] sysdir for an explanation of these directory codewords. You may also specify an actual directory name, such as C: \mydir.
verbose is specified when you suspect network problems. It provides more detailed output that may help you diagnose the problem.

## Remarks and examples

Community-contributed additions to Stata are called packages and can add remarkable abilities to Stata. Community-contributed packages are updated by their developers, just as official Stata software is updated by StataCorp.

Do not confuse ado update with update. Use ado update to update community-contributed files. Use update to update the components (including ado-files) of the official Stata software. To use either command, you must be connected to the Internet.

Although Stata checks for updates automatically and can even be set to update automatically in Stata for Windows and Stata for Mac, you must remember to type ado update. Doing this regularly can help prevent errors that occur when accidentally running older versions of community-contributed packages.

Remarks are presented under the following headings:
Using ado update
Notes for developers

## Using ado update

The first time you try ado update, type

- ado update
ado update without the update option produces a report but does not update any files. The first time you run ado update, you may see messages such as

```
. ado update
note: ado update updates community-contributed files; type update to check for
    updates to official Stata.
Checking status of installed packages...
    [1] sjlatex at http://svn.stata.com/svn/press/press/production:
            installed package is up to date
        (output omitted)
```

Having the same packages installed multiple times can lead to confusion; ado update cleans that up.

To update all of your community-contributed packages that need updating, type

```
. ado update, update
```

You can also update a subset of your packages. You can specify one or many packages after the ado update command. You can even use wildcards such as st* to mean all packages that start with st or st*8 to mean all packages that start with st and end with 8 . For example, if the report indicated package st0008 had an update available, type the following to update that one package:

```
. ado update st0008, update
```

## Notes for developers

ado update reports whether an installed package is up to date by comparing its distribution date with that of the package available over the web.

If you are distributing software, include the line
d Distribution-Date: date
somewhere in your .pkg file. The capitalization of Distribution-Date does not matter, but include the hyphen and the colon as shown. Code the date in either of two formats:
all numeric: yyyymmdd, for example, 20200701
Stata standard: ddMONyyyy, for example, 01jul2020

## Stored results

ado update stores the following in $r()$ :
Macros
$r$ (pkglist) a space-separated list of package names that need updating (update not specified) or that were updated (update specified)

## Also see

## Title

ameans - Arithmetic, geometric, and harmonic means

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| Acknowledgments | References | Also see |  |

## Description

ameans computes the arithmetic, geometric, and harmonic means, with their corresponding confidence intervals, for each variable in varlist or for all the variables in the data if varlist is not specified. gmeans and hmeans are synonyms for ameans.

## Quick start

Arithmetic, geometric, and harmonic means of variable v 1 ameans v1

Same as above, but for variables v1, v2, and v3
ameans v1 v2 v3
Means for all variables in the dataset
ameans
Add $n$ to each observation before calculating means
ameans v1, add(n)
Add $n$ to each observation only for variables with at least 1 nonpositive value ameans v1 v2 v3, add(n) only

Request $99 \%$ confidence intervals
ameans v1, level(99)

## Menu

Statistics $>$ Summaries, tables, and tests $>$ Summary and descriptive statistics $>$ Arith./geometric/harmonic means

## Syntax

```
ameans [varlist] [if] [in] [weight] [, options]
```

options

## Description

Main
add (\#)
only
level(\#)
add \# to each variable in varlist
add \# only to variables with nonpositive values
set confidence level; default is level (95)
by and collect are allowed; see [D] by.
aweights and fweights are allowed; see [U] 11.1.6 weight.

## Options

$\qquad$ Main
add(\#) adds the value \# to each variable in varlist before computing the means and confidence intervals. This option is useful when analyzing variables with nonpositive values.
only modifies the action of the add(\#) option so that it adds \# only to variables with at least one nonpositive value.
level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

## Remarks and examples

## $>$ Example 1

We have a dataset containing 8 observations on a variable named x . The eight values are 5, 4, $-4,-5,0,0$, missing, and 7 .

| ameans x <br> Variable | Type | Obs | Mean | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| x | Arithmetic | 7 | 1 | -3.204405 | 5.204405 |
|  | Geometric | 3 | 5.192494 | 2.57899 | 10.45448 |
|  | Harmonic | 3 | 5.060241 | 3.023008 | 15.5179 |

| . ameans $\mathrm{x}, \operatorname{add}(5)$ |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| Variable | Type | Obs | Mean | [95\% conf. interval] |  |
| x | Arithmetic | 7 | 6 | 1.795595 | $10.2044 *$ |
|  | Geometric | 6 | 5.477226 | 2.1096 | $14.22071^{*}$ |
|  | Harmonic | 6 | 3.540984 | . | .$*$ |

[^0]The number of observations displayed for the arithmetic mean is the number of nonmissing observations. The number of observations displayed for the geometric and harmonic means is the number of nonmissing, positive observations. Specifying the add (5) option produces 3 more positive observations. The confidence interval for the harmonic mean is not reported; see Methods and formulas below.

## Video example

Descriptive statistics in Stata

## Stored results

ameans stores the following in r() :
Scalars

| r (N) | number of nonmissing observations; used for arithmetic mean |
| :---: | :---: |
| r(N_pos) | number of nonmissing positive observations; used for geometric and harmonic means |
| r (mean) | arithmetic mean |
| r(lb) | lower bound of confidence interval for arithmetic mean |
| $\mathrm{r}(\mathrm{ub})$ | upper bound of confidence interval for arithmetic mean |
| r(Var) | variance of untransformed data |
| r (mean_g) | geometric mean |
| r(lb_g) | lower bound of confidence interval for geometric mean |
| r (ub_g) | upper bound of confidence interval for geometric mean |
| r (Var_g) | variance of $\ln x_{i}$ |
| r (mean_h) | harmonic mean |
| r(lb_h) | lower bound of confidence interval for harmonic mean |
| r (ub_h) | upper bound of confidence interval for harmonic mean |
| r (Var_h) | variance of $1 / x_{i}$ |
| r(level) | confidence level of confidence interval |

## Methods and formulas

See Armitage, Berry, and Matthews (2002) or Snedecor and Cochran (1989). For a history of the concept of the mean, see Plackett (1958).

When restricted to the same set of values (that is, to positive values), the arithmetic mean $(\bar{x})$ is greater than or equal to the geometric mean, which in turn is greater than or equal to the harmonic mean. Equality holds only if all values within a sample are equal to a positive constant.

The arithmetic mean and its confidence interval are identical to those provided by ci; see $[\mathrm{R}]$ ci.
To compute the geometric mean, ameans first creates $u_{j}=\ln x_{j}$ for all positive $x_{j}$. The arithmetic mean of the $u_{j}$ and its confidence interval are then computed as in ci. Let $\bar{u}$ be the resulting mean, and let $[L, U]$ be the corresponding confidence interval. The geometric mean is then $\exp (\bar{u})$, and its confidence interval is $[\exp (L), \exp (U)]$.

The same procedure is followed for the harmonic mean, except that then $u_{j}=1 / x_{j}$. The harmonic mean is then $1 / \bar{u}$, and its confidence interval is $[1 / U, 1 / L]$ if $L$ is greater than zero. If $L$ is not greater than zero, this confidence interval is not defined, and missing values are reported.

When weights are specified, ameans applies the weights to the transformed values, $u_{j}=\ln x_{j}$ and $u_{j}=1 / x_{j}$, respectively, when computing the geometric and harmonic means. For details on how the weights are used to compute the mean and variance of the $u_{j}$, see [R] summarize. Without weights, the formula for the geometric mean reduces to

$$
\exp \left\{\frac{1}{n} \sum_{j} \ln \left(x_{j}\right)\right\}
$$

Without weights, the formula for the harmonic mean is

$$
\frac{n}{\sum_{j} \frac{1}{x_{j}}}
$$

## Acknowledgments

This improved version of ameans is based on the gmci command (Carlin, Vidmar, and Ramalheira 1998) and was written by John Carlin of the Murdoch Children's Research Institute and the University of Melbourne; Suzanna Vidmar of the University of Melbourne; and Carlos Ramalheira of Coimbra University Hospital, Portugal.

## Title

anova - Analysis of variance and covariance

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | References |
| Also see |  |  |  |

## Description

The anova command fits analysis-of-variance (ANOVA) and analysis-of-covariance (ANCOVA) models for balanced and unbalanced designs, including designs with missing cells; for repeated-measures ANOVA; and for factorial, nested, or mixed designs.

## Quick start

One-way ANOVA model of $y$ for factor a anova y a

Two-way full-factorial ANOVA for factors $a$ and $b$ anova y a b a\#b

Same as above
anova y a\#\#b
ANCOVA model including continuous variable x
anova y a\#\#b c.x
Factor b nested within a
anova y a / bla /
Repeated-measures ANOVA with repeated variable rvar
anova y a rvar, repeated(rvar)
Repeated-measures ANOVA with subjects, idvar, observed at each level of rvar anova y a / idvarla rvar rvar\#a, repeated(rvar)

## Menu

Statistics $>$ Linear models and related $>$ ANOVA/MANOVA $>$ Analysis of variance and covariance

## Syntax

$$
\text { anova varname }[\text { termlist }][\text { if }][\text { in }][\text { weight }][\text {, options }]
$$

where termlist is a factor-variable list (see [U] 11.4.3 Factor variables) with the following additional features:

- Variables are assumed to be categorical; use the c. factor-variable operator to override this.
- The $\mid$ symbol (indicating nesting) may be used in place of the \# symbol (indicating interaction).
- The / symbol is allowed after a term and indicates that the following term is the error term for the preceding terms.
options
Model
repeated (varlist)
partial
sequential
noconstant
dropemptycells
Adv. model
bse (term)
bseunit (varname)
grouping (varname)

Description
variables in terms that are repeated-measures variables
use partial (or marginal) sums of squares
use sequential sums of squares
suppress constant term
drop empty cells from the design matrix
between-subjects error term in repeated-measures ANOVA variable representing lowest unit in the between-subjects error term grouping variable for computing pooled covariance matrix
bootstrap, by, collect, fp, jackknife, and statsby are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
aweights are not allowed with the jackknife prefix; see [R] jackknife.
aweights and fweights are allowed; see [U] 11.1.6 weight.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

$\qquad$ Model
repeated (varlist) indicates the names of the categorical variables in the terms that are to be treated as repeated-measures variables in a repeated-measures ANOVA or ANCOVA.
partial presents the ANOVA table using partial (or marginal) sums of squares. This setting is the default. Also see the sequential option.
sequential presents the ANOVA table using sequential sums of squares.
noconstant suppresses the constant term (intercept) from the ANOVA or regression model.
dropemptycells drops empty cells from the design matrix. If c (emptycells) is set to keep (see $[\mathrm{R}]$ set emptycells), this option temporarily resets it to drop before running the ANOVA model. If c (emptycells) is already set to drop, this option does nothing.
bse (term) indicates the between-subjects error term in a repeated-measures ANOVA. This option is needed only in the rare case when the anova command cannot automatically determine the between-subjects error term.
bseunit (varname) indicates the variable representing the lowest unit in the between-subjects error term in a repeated-measures ANOVA. This option is rarely needed because the anova command automatically selects the first variable listed in the between-subjects error term as the default for this option.
grouping (varname) indicates a variable that determines which observations are grouped together in computing the covariance matrices that will be pooled and used in a repeated-measures ANOVA. This option is rarely needed because the anova command automatically selects the combination of all variables except the first (or as specified in the bseunit() option) in the between-subjects error term as the default for grouping observations.

## Remarks and examples

Remarks are presented under the following headings:

Introduction<br>One-way ANOVA<br>Two-way ANOVA<br>$N$-way ANOVA<br>Weighted data<br>ANCOVA<br>Nested designs<br>Mixed designs<br>Latin-square designs<br>Repeated-measures ANOVA<br>Video examples

## Introduction

anova uses least squares to fit the linear models known as ANOVA or ANCOVA (henceforth referred to simply as ANOVA models).

If you want to fit one-way ANOVA models, you may find the oneway or loneway command more convenient; see $[R]$ oneway and $[R]$ loneway. If you are interested in MANOVA or MANCOVA, see [MV] manova.

Structural equation modeling provides a more general framework for fitting ANOVA models; see the Stata Structural Equation Modeling Reference Manual.

ANOVA was pioneered by Fisher. It features prominently in his texts on statistical methods and his design of experiments $(1925,1935)$. Many books discuss ANOVA; see, for instance, Altman (1991); van Belle et al. (2004); Cobb (1998); Snedecor and Cochran (1989); or Winer, Brown, and Michels (1991). For a classic source, see Scheffé (1959). Kennedy and Gentle (1980) discuss ANOVA's computing problems. Edwards (1985) is concerned primarily with the relationship between multiple regression and ANOVA. Acock (2023, chap. 9) and Baldwin (2019, chap. 5 and 6) illustrate their discussion with Stata output. Repeated-measures ANOVA is discussed in Winer, Brown, and Michels (1991) and Milliken and Johnson (2009). Pioneering work in repeated-measures ANOVA can be found in Box (1954); Geisser and Greenhouse (1958); Huynh and Feldt (1976); and Huynh (1978). For a Stata-specific discussion of ANOVA contrasts, see Mitchell (2021, chap. 7-9; 2015, chap. 4-9).

## One-way ANOVA

anova, entered without options, performs and reports standard ANOVA. For instance, to perform a one-way layout of a variable called endog on exog, you would type anova endog exog.

## > Example 1: One-way ANOVA

We run an experiment varying the amount of fertilizer used in growing apple trees. We test four concentrations, using each concentration in three groves of 12 trees each. Later in the year, we measure the average weight of the fruit.

If all had gone well, we would have had 3 observations on the average weight for each of the four concentrations. Instead, two of the groves were mistakenly leveled by a confused man on a large bulldozer. We are left with the following data:

```
. use https://www.stata-press.com/data/r18/apple
(Apple trees)
. list, abbrev(10) sepby(treatment)
```

| treatment | weight |
| ---: | ---: |
| 1 | 117.5 |
| 1 | 113.8 |
| 1 | 104.4 |
| 2 | 48.9 |
| 2 | 50.4 |
| 2 | 58.9 |
| 3 | 70.4 |
| 3 | 86.9 |
| 4 | 87.7 |
| 4 | 67.3 |

To obtain one-way ANOVA results, we type . anova weight treatment

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 10 \\ 9.07002 \end{array}$ | R-squared |  | $\begin{aligned} & 0.9147 \\ & 0.8721 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 5295.5443 | 3 | 1765.1814 | 21.46 | 0.0013 |
| treatment | 5295.5443 | 3 | 1765.1814 | 21.46 | 0.0013 |
| Residual | 493.59167 | 68 | 82.265278 |  |  |
| Total | 5789.136 | 96 | 643.23733 |  |  |

We find significant (at better than the $1 \%$ level) differences among the four concentrations.
Although the output is a usual ANOVA table, let's run through it anyway. Above the table is a summary of the underlying regression. The model was fit on 10 observations, and the root mean squared error (Root MSE) is 9.07. The $R^{2}$ for the model is 0.9147 , and the adjusted $R^{2}$ is 0.8721 .

The first line of the table summarizes the model. The sum of squares (Partial SS) for the model is 5295.5 with 3 degrees of freedom (df). This line results in a mean square (MS) of 5295.5/3 $\approx 1765.2$. The corresponding $F$ statistic is 21.46 and has a significance level of 0.0013 . Thus, the model appears to be significant at the $0.13 \%$ level.

The next line summarizes the first (and only) term in the model, treatment. Because there is only one term, the line is identical to that for the overall model.

The third line summarizes the residual. The residual sum of squares is 493.59 with 6 degrees of freedom, resulting in a mean squared error of 82.27 . The square root of this latter number is reported as the Root MSE.

The model plus the residual sum of squares equals the total sum of squares, which is reported as 5789.1 in the last line of the table. This is the total sum of squares of weight after removal of the mean. Similarly, the model plus the residual degrees of freedom sum to the total degrees of freedom, 9. Remember that there are 10 observations. Subtracting 1 for the mean, we are left with 9 total degrees of freedom.

## - Technical note

Rather than using the anova command, we could have performed this analysis by using the oneway command. Example 1 in $[R]$ oneway repeats this same analysis. You may wish to compare the output.

The regress command (see [R] regress) is used to fit the underlying regression model corresponding to an ANOVA model fit using the anova command. Type regress after anova to see the coefficients, standard errors, etc., of the regression model for the last run of anova.
> Example 2: Regression table from a one-way ANOVA
Returning to the apple tree experiment, we found that the fertilizer concentration appears to significantly affect the average weight of the fruit. Although that finding is interesting, we next want to know which concentration appears to grow the heaviest fruit. One way to find out is by examining the underlying regression coefficients.

See $[R]$ regress for an explanation of how to read this table. The baselevels option of regress displays a row indicating the base category for our categorical variable, treatment. In summary, we find that concentration 1, the base (omitted) group, produces significantly heavier fruits than concentration 2 , 3 , and 4 ; concentration 2 produces the lightest fruits; and concentrations 3 and 4 appear to be roughly equivalent.

## > Example 3: ANOVA replay

We previously typed anova weight treatment to produce and display the ANOVA table for our apple tree experiment. Typing regress displays the regression coefficients. We can redisplay the ANOVA table by typing anova without arguments:
. anova

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 10 \\ 9.07002 \end{array}$ | 2 R-squ | R -squared | $\begin{aligned} & 0.9147 \\ & 0.8721 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 5295.5443 | 3 | 1765.1814 | 21.46 | 0.0013 |
| treatment | 5295.5443 | 3 | 1765.1814 | 21.46 | 0.0013 |
| Residual | 493.59167 | 6 | 82.265278 |  |  |
| Total | 5789.136 | 9 | 643.23733 |  |  |

## Two-way ANOVA

You can include multiple explanatory variables with the anova command, and you can specify interactions by placing '\#' between the variable names. For instance, typing anova y a b performs a two-way layout of y on a and b . Typing anova y a b a\#b performs a full two-way factorial layout. The shorthand anova y a\#\#b does the same.

With the default partial sums of squares, when you specify interacted terms, the order of the terms does not matter. Typing anova y a b a\#b is the same as typing anova y bab\#a.
> Example 4: Two-way factorial ANOVA
The classic two-way factorial ANOVA problem, at least as far as computer manuals are concerned, is a two-way ANOVA design from Afifi and Azen (1979).

Fifty-eight patients, each suffering from one of three different diseases, were randomly assigned to one of four different drug treatments, and the change in their systolic blood pressure was recorded. Here are the data:

|  | Disease 1 | Disease 2 | Disease 3 |
| :--- | :--- | :--- | :--- |
| Drug 1 | $42,44,36$ | $33,26,33$ | $31,-3,25$ |
|  | $13,19,22$ | 21 | 25,24 |
| Drug 2 | $28,23,34$ | $34,33,31$ | $3,26,28$ |
|  | 42,13 | 36 | $32,4,16$ |
| Drug 3 | $1,29,19$ | $11,9,7$ | $21,1,9$ |
|  |  | $1,-6$ | 3 |
| Drug 4 | $24,9,22$ | $27,12,12$ | $22,7,25$ |
|  | $-2,15$ | $-5,16,15$ | 5,12 |

Let's assume that we have entered these data into Stata and stored the data as systolic.dta. Below we use the data, list the first 10 observations, summarize the variables, and tabulate the control variables:

```
. use https://www.stata-press.com/data/r18/systolic
(Systolic blood pressure data)
. list in 1/10
```

|  | drug | disease | systolic |
| :---: | ---: | ---: | ---: |
| 1. | 1 | 1 | 42 |
| 2. | 1 | 1 | 44 |
| 3. | 1 | 1 | 36 |
| 4. | 1 | 1 | 13 |
| 5. | 1 | 1 | 19 |
| 6. | 1 | 1 | 22 |
| 7. | 1 | 2 | 33 |
| 8. | 1 | 2 | 26 |
| 9. | 1 | 2 | 33 |
| 10. | 1 | 2 | 21 |

. summarize

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| drug | 58 | 2.5 | 1.158493 | 1 | 4 |
| disease | 58 | 2.017241 | .8269873 | 1 | 3 |
| systolic | 58 | 18.87931 | 12.80087 | -6 | 44 |

. tabulate drug disease

|  | Patient's disease |  |  |  |
| ---: | :---: | :---: | :---: | ---: |
| Drug used | 1 | 2 | 3 | Total |
| 1 | 6 | 4 | 5 | 15 |
| 2 | 5 | 4 | 6 | 15 |
| 3 | 3 | 5 | 4 | 12 |
| 4 | 5 | 6 | 5 | 16 |
| Total | 19 | 19 | 20 | 58 |

Each observation in our data corresponds to one patient, and for each patient we record drug, disease, and the increase in the systolic blood pressure, systolic. The tabulation reveals that the data are not balanced-there are not equal numbers of patients in each drug-disease cell. Stata does not require that the data be balanced. We can perform a two-way factorial ANOVA by typing
. anova systolic drug disease drug\#disease

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 58 \\ 10.5096 \end{array}$ | R-squared = <br> Adj R-squared $=$ |  | $\begin{aligned} & 0.4560 \\ & 0.3259 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 4259.3385 | 113 | 387.21259 | 3.51 | 0.0013 |
| drug | 2997.4719 | 39 | 999.15729 | 9.05 | 0.0001 |
| disease | 415.87305 | 2 | 207.93652 | 1.88 | 0.1637 |
| drug\#disease | 707.26626 | 61 | 117.87771 | 1.07 | 0.3958 |
| Residual | 5080.8167 | $46 \quad 1$ | 110.45254 |  |  |
| Total | 9340.1552 | $57 \quad 1$ | 163.86237 |  |  |

Although Stata's table command does not perform ANOVA, it can produce useful summary tables of your data (see [R] table):

```
. table drug disease, statistic(mean systolic) nformat(%8.2f)
```

|  | Patient's disease |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | Total |
| Drug used |  |  |  |  |
| 1 | 29.33 | 28.25 | 20.40 | 26.07 |
| 2 | 28.00 | 33.50 | 18.17 | 25.53 |
| 3 | 16.33 | 4.40 | 8.50 | 8.75 |
| 4 | 13.60 | 12.83 | 14.20 | 13.50 |
| Total | 22.79 | 18.21 | 15.80 | 18.88 |

These are simple means and are not influenced by our anova model. More useful is the margins command (see [R] margins) that provides marginal means and adjusted predictions. Because drug is the only significant factor in our ANOVA, we now examine the adjusted marginal means for drug.

```
. margins drug, asbalanced
Adjusted predictions Number of obs = 58
Expression: Linear prediction, predict()
At: drug (asbalanced)
        disease (asbalanced)
```

|  | Delta-method |  |  |  |  | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| drug |  |  |  |  |  |  |
| 1 | 25.99444 | 2.751008 | 9.45 | 0.000 | 20.45695 | 31.53194 |
| 2 | 26.55556 | 2.751008 | 9.65 | 0.000 | 21.01806 | 32.09305 |
| 3 | 9.744444 | 3.100558 | 3.14 | 0.003 | 3.503344 | 15.98554 |
| 4 | 13.54444 | 2.637123 | 5.14 | 0.000 | 8.236191 | 18.8527 |

These adjusted marginal predictions are not equal to the simple drug means (see the totals from the table command); they are based upon predictions from our ANOVA model. The asbalanced option of margins corresponds with the interpretation of the $F$ statistic produced by ANOVA-each cell is given equal weight regardless of its sample size (see the following three technical notes). You can omit the asbalanced option and obtain predictive margins that take into account the unequal sample sizes of the cells.
. margins drug
Predictive margins $\quad$ Number of obs $=58$
Expression: Linear prediction, predict()

|  | Delta-method <br> std. err. |  |  |  | t | $\mathrm{P}>\|\mathrm{t}\|$ |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Margin | [95\%conf. interval] |  |  |  |  |  |
| drug |  |  |  |  |  |  |
| 1 | 25.89799 | 2.750533 | 9.42 | 0.000 | 20.36145 | 31.43452 |
| 2 | 26.41092 | 2.742762 | 9.63 | 0.000 | 20.89003 | 31.93181 |
| 3 | 9.722989 | 3.099185 | 3.14 | 0.003 | 3.484652 | 15.96132 |
| 4 | 13.55575 | 2.640602 | 5.13 | 0.000 | 8.24049 | 18.871 |

## Technical note

How do you interpret the significance of terms like drug and disease in unbalanced data? If you are familiar with SAS, the sums of squares and the $F$ statistic reported by Stata correspond to SAS type III sums of squares. (Stata can also calculate sequential sums of squares, but we will postpone that topic for now.)

Let's think in terms of the following table:

|  | Disease 1 | Disease 2 | Disease 3 |  |
| :--- | :---: | :---: | :---: | :---: |
| Drug 1 | $\mu_{11}$ | $\mu_{12}$ | $\mu_{13}$ | $\mu_{1}$. |
| Drug 2 | $\mu_{21}$ | $\mu_{22}$ | $\mu_{23}$ | $\mu_{2}$ |
| Drug 3 | $\mu_{31}$ | $\mu_{32}$ | $\mu_{33}$ | $\mu_{3}$ |
| Drug 4 | $\mu_{41}$ | $\mu_{42}$ | $\mu_{43}$ | $\mu_{4}$ |
|  | $\mu \cdot 1$ | $\mu_{\cdot 2}$ | $\mu \cdot 3$ | $\mu \cdot$. |

In this table, $\mu_{i j}$ is the mean increase in systolic blood pressure associated with drug $i$ and disease $j$, while $\mu_{i}$. is the mean for drug $i, \mu_{\cdot j}$ is the mean for disease $j$, and $\mu$.. is the overall mean.

If the data are balanced, meaning that there are equal numbers of observations going into the calculation of each mean $\mu_{i j}$, the row means, $\mu_{i}$, are given by

$$
\mu_{i}=\frac{\mu_{i 1}+\mu_{i 2}+\mu_{i 3}}{3}
$$

In our case, the data are not balanced, but we define the $\mu_{i}$. according to that formula anyway. The test for the main effect of drug is the test that

$$
\mu_{1 .}=\mu_{2}=\mu_{3 .}=\mu_{4}
$$

To be absolutely clear, the $F$ test of the term drug, called the main effect of drug, is formally equivalent to the test of the three constraints:

$$
\begin{aligned}
& \frac{\mu_{11}+\mu_{12}+\mu_{13}}{3}=\frac{\mu_{21}+\mu_{22}+\mu_{23}}{3} \\
& \frac{\mu_{11}+\mu_{12}+\mu_{13}}{3}=\frac{\mu_{31}+\mu_{32}+\mu_{33}}{3} \\
& \frac{\mu_{11}+\mu_{12}+\mu_{13}}{3}=\frac{\mu_{41}+\mu_{42}+\mu_{43}}{3}
\end{aligned}
$$

In our data, we obtain a significant $F$ statistic of 9.05 and thus reject those constraints.

## - Technical note

Stata can display the symbolic form underlying the test statistics it presents, as well as display other test statistics and their symbolic forms; see Obtaining symbolic forms in [R] anova postestimation. Here is the result of requesting the symbolic form for the main effect of drug in our data:

```
. test drug, symbolic
drug
    1 -(r2+r3+r4)
    2 r2
    r3
    r4
disease
    10
    2 0
    3 0
drug#disease
    1 1 -1/3 (r2+r3+r4)
        1 2 -1/3 (r2+r3+r4)
        1 3 -1/3 (r2+r3+r4)
        2 1 1/3 r2
        2 2 1/3 r2
        2 3 1/3 r2
        3 1 1/3 r3
        3 2 1/3 r3
        3 3 1/3 r3
        4 1 1/3 r4
        4 2 1/3 r4
    4 3 1/3 r4
_cons
```

This says exactly what we said in the previous technical note.

## - Technical note

Saying that there is no main effect of a variable is not the same as saying that it has no effect at all. Stata's ability to perform ANOVA on unbalanced data can easily be put to ill use.

For example, consider the following table of the probability of surviving a bout with one of two diseases according to the drug administered to you:

|  | Disease 1 | Disease 2 |
| :--- | :---: | :---: |
| Drug 1 | 1 | 0 |
| Drug 2 | 0 | 1 |

If you have disease 1 and are administered drug 1, you live. If you have disease 2 and are administered drug 2, you live. In all other cases, you die.

This table has no main effects of either drug or disease, although there is a large interaction effect. You might now be tempted to reason that because there is only an interaction effect, you would be indifferent between the two drugs in the absence of knowledge about which disease infects you. Given an equal chance of having either disease, you reason that it does not matter which drug is administered to you-either way, your chances of surviving are 0.5 .

You may not, however, have an equal chance of having either disease. If you knew that disease 1 was 100 times more likely to occur in the population, and if you knew that you had one of the two diseases, you would express a strong preference for receiving drug 1.

When you calculate the significance of main effects on unbalanced data, you must ask yourself why the data are unbalanced. If the data are unbalanced for random reasons and you are making predictions for a balanced population, the test of the main effect makes perfect sense. If, however, the data are unbalanced because the underlying populations are unbalanced and you are making predictions for such unbalanced populations, the test of the main effect may be practically-if not statistically - meaningless.

## > Example 5: ANOVA with missing cells

Stata can perform ANOVA not only on unbalanced populations, but also on populations that are so unbalanced that entire cells are missing. For instance, using our systolic blood pressure data, let's refit the model eliminating the drug 1 -disease 1 cell. Because anova follows the same syntax as all other Stata commands, we can explicitly specify the data to be used by typing the if qualifier at the end of the anova command. Here we want to use the data that are not for drug 1 and disease 1 :

|  | $\begin{aligned} \text { Number of obs } & = \\ \text { Root MSE } & = \end{aligned}$ | $\begin{array}{r} 52 \\ 10.1615 \end{array}$ | R-squared = <br> Adj R-squared = |  | $\begin{aligned} & 0.4545 \\ & 0.3215 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 3527.959 | 10 | 352.7959 | 3.42 | 0.0025 |
| drug | 2686.5783 | 38 | 895.52611 | 8.67 | 0.0001 |
| disease | 327.7926 | 2 | 163.8963 | 1.59 | 0.2168 |
| drug\#disease | 703.0076 | 51 | 140.60152 | 1.36 | 0.2586 |
| Residual | 4233.4833 | 41 1 | 103.25569 |  |  |
| Total | 7761.4423 | 51 | 152.18514 |  |  |

Here we used drug\#\#disease as a shorthand for drug disease drug\#disease.

## - Technical note

The test of the main effect of drug in the presence of missing cells is more complicated than that for unbalanced data. Our underlying tableau now has the following form:

|  | Disease 1 | Disease 2 | Disease 3 |  |
| :--- | :---: | :---: | :---: | :---: |
| Drug 1 |  | $\mu_{12}$ | $\mu_{13}$ |  |
| Drug 2 | $\mu_{21}$ | $\mu_{22}$ | $\mu_{23}$ | $\mu_{2}$. |
| Drug 3 | $\mu_{31}$ | $\mu_{32}$ | $\mu_{33}$ | $\mu_{3}$. |
| Drug 4 | $\mu_{41}$ | $\mu_{42}$ | $\mu_{43}$ | $\mu_{4}$. |
|  |  | $\mu_{\cdot 2}$ | $\mu_{\cdot 3}$ |  |

The hole in the drug 1-disease 1 cell indicates that the mean is unobserved. Considering the main effect of drug, the test is unchanged for the rows in which all the cells are defined:

$$
\mu_{2}=\mu_{3 .}=\mu_{4}
$$

The first row, however, requires special attention. Here we want the average outcome for drug 1, which is averaged only over diseases 2 and 3 , to be equal to the average values of all other drugs averaged over those same two diseases:

$$
\frac{\mu_{12}+\mu_{13}}{2}=\frac{\left(\mu_{22}+\mu_{23}\right) / 2+\left(\mu_{32}+\mu_{33}\right) / 2+\left(\mu_{42}+\mu_{43}\right) / 2}{3}
$$

Thus, the test contains three constraints:

$$
\begin{array}{rcc}
\frac{\mu_{21}+\mu_{22}+\mu_{23}}{3} & = & \frac{\mu_{31}+\mu_{32}+\mu_{33}}{3} \\
\frac{\mu_{21}+\mu_{22}+\mu_{23}}{3} & = & \frac{\mu_{41}+\mu_{42}+\mu_{43}}{3} \\
\frac{\mu_{12}+\mu_{13}}{2} & = & \frac{\mu_{22}+\mu_{23}+\mu_{32}+\mu_{33}+\mu_{42}+\mu_{43}}{6}
\end{array}
$$

Stata can calculate two types of sums of squares, partial and sequential. If you do not specify which sums of squares to calculate, Stata calculates partial sums of squares. The technical notes above have gone into great detail about the definition and use of partial sums of squares. Use the sequential option to obtain sequential sums of squares.

## - Technical note

Before we illustrate sequential sums of squares, consider one more feature of the partial sums. If you know how such things are calculated, you may worry that the terms must be specified in some particular order, that Stata would balk or, even worse, produce different results if you typed, say, anova systolic drug\#disease drug disease rather than anova systolic drug disease drug\#disease. We assure you that is not the case.

When you type a model, Stata internally reorganizes the terms, forms the cross-product matrix, inverts it, converts the result to an upper-Hermite form, and then performs the hypothesis tests. As a final touch, Stata reports the results in the same order that you typed the terms.

## > Example 6: Sequential sums of squares

We wish to estimate the effects on systolic blood pressure of drug and disease by using sequential sums of squares. We want to introduce disease first, then drug, and finally, the interaction of drug and disease:

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 58 \\ 10.5096 \end{array}$ | R -squared $=$ <br> Adj R -squared $=$ |  | $\begin{aligned} & 0.4560 \\ & 0.3259 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Seq. SS | df | MS | F | Prob>F |
| Model | 4259.3385 | 113 | 387.21259 | 3.51 | 0.0013 |
| disease | 488.63938 | 2 | 244.31969 | 2.21 | 0.1210 |
| drug | 3063.4329 | 31 | 1021.1443 | 9.25 | 0.0001 |
| disease\#drug | 707.26626 | 61 | 117.87771 | 1.07 | 0.3958 |
| Residual | 5080.8167 | $46 \quad 1$ | 110.45254 |  |  |
| Total | 9340.1552 | $57 \quad 1$ | 163.86237 |  |  |

The $F$ statistic on disease is now 2.21 . When we fit this same model by using partial sums of squares, the statistic was 1.88 .

## N-way ANOVA

You may include high-order interaction terms, such as a third-order interaction between the variables $\mathrm{A}, \mathrm{B}$, and C, by typing A\#B\#C.

## > Example 7: Three-way factorial ANOVA

We wish to determine the operating conditions that maximize yield for a manufacturing process. There are three temperature settings, two chemical supply companies, and two mixing methods under investigation. Three observations are obtained for each combination of these three factors.

Sorted by:

We wish to perform a three-way factorial ANOVA. We could type

```
. anova yield temp chem temp#chem meth temp#meth chem#meth temp#chem#meth
```

but prefer to use the \#\# factor-variable operator for brevity.

|  | $\begin{aligned} \text { Number of obs } & = \\ \text { Root MSE } & = \end{aligned}$ | $\begin{array}{r} 36 \\ 2.62996 \end{array}$ | R-squared =Adj R-squared = |  | $\begin{aligned} & 0.5474 \\ & 0.3399 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 200.75 | 11 | 18.25 | 2.64 | 0.0227 |
| temperature | 30.5 | 2 | 15.25 | 2.20 | 0.1321 |

| Total | 366.75 | 35 | 10.478571 |  |  |

The interaction between temperature and method appears to be the important story in these data. A table of means for this interaction is given below.

| table method temp, statistic(mean yield) nformat ( |  |  |  |  |
| :--- | :---: | :---: | :---: | ---: |
|  | Machine temperature setting <br> Low |  |  |  |
|  | Medium | High | Total |  |
| Mixing method |  |  |  |  |
| Stir | 7.50 | 6.00 | 6.00 | 6.50 |
| Fold | 5.50 | 9.00 | 11.50 | 8.67 |
| Total | 6.50 | 7.50 | 8.75 | 7.58 |

Here our ANOVA is balanced (each cell has the same number of observations), and we obtain the same values as in the table above (but with additional information such as confidence intervals) by using the margins command. Because our ANOVA is balanced, using the asbalanced option with margins would not produce different results. We request the predictive margins for the two terms that appear significant in our ANOVA: temperature\#method and method.

| ```Predictive margins Number of obs = 36 Expression: Linear prediction, predict()``` |  |  |  |  |  |  |

| Stir | 6.5 | . 6198865 | 10.49 | 0.000 | 5.220617 | 7.779383 |
| Fold | 8.666667 | . 6198865 | 13.98 | 0.000 | 7.387284 | 9.946049 |

We decide to use the folding method of mixing and a high temperature in our manufacturing process.

## Weighted data

Like all estimation commands, anova can produce estimates on weighted data. See [U] 11.1.6 weight for details on specifying the weight.

## > Example 8: Three-way factorial ANOVA on grouped data

We wish to investigate the prevalence of byssinosis, a form of pneumoconiosis that can afflict workers exposed to cotton dust. We have data on 5,419 workers in a large cotton mill. We know whether each worker smokes, his or her race, and the dustiness of the work area. The variables are

| smokes | smoker or nonsmoker in the last five years |
| :--- | :--- |
| race | white or other |
| workplace | 1 (most dusty), 2 (less dusty), 3 (least dusty) |

We wish to fit an ANOVA model explaining the prevalence of byssinosis according to a full factorial model of smokes, race, and workplace.

The data are unbalanced. Moreover, although we have data on 5,419 workers, the data are grouped according to the explanatory variables, along with some other variables, resulting in 72 observations. For each observation, we know the number of workers in the group (pop), the prevalence of byssinosis (prob), and the values of the three explanatory variables. Thus, we wish to fit a three-way factorial model on grouped data.

We begin by showing a bit of the data, which are from Higgins and Koch (1977).

Sorted by:
. list in 1/5, abbrev(10) divider

| smokes | race | workplace | pop | prob |
| :---: | :---: | ---: | ---: | ---: |
| Yes | White | Most | 40 | .075 |
| Yes | White | Less | 74 | 0 |
| Yes | White | Least | 260 | .0076923 |
| Yes | Other | Most | 164 | .152439 |
| Yes | Other | Less | 88 | 0 |

The first observation in the data represents a group of 40 white workers who smoke and work in a "most" dusty work area. Of those 40 workers, $7.5 \%$ have byssinosis. The second observation represents a group of 74 white workers who also smoke but who work in a "less" dusty environment. None of those workers has byssinosis.

Almost every Stata command allows weights. Here we want to weight the data by pop. We can, for instance, make a table of the number of workers by their smoking status and race:

| Smokes | Other | White | Total |
| :---: | :---: | :---: | :---: |
| No | 799 | 1,431 | 2,230 |
| Yes | 1,104 | 2,085 | 3,189 |
| Total | 1,903 | 3,516 | 5,419 |

The [ $f \mathrm{w}=\mathrm{pop}$ ] at the end of the tabulate command tells Stata to count each observation as representing pop persons. When making the tally, tabulate treats the first observation as representing 40 workers, the second as representing 74 workers, and so on.

Similarly, we can make a table of the dustiness of the workplace:
. tabulate workplace [fw=pop]

| Dustiness <br> of <br> workplace | Freq. | Percent | Cum. |
| ---: | ---: | ---: | ---: |
| Least | 3,450 | 63.66 | 63.66 |
| Less | 1,300 | 23.99 | 87.65 |
| Most | 669 | 12.35 | 100.00 |
| Total | 5,419 | 100.00 |  |

We can discover the average incidence of byssinosis among these workers by typing . summarize prob [fw=pop]

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| prob | 5,419 | .0304484 | .0567373 | 0 | .287037 |

We discover that $3.04 \%$ of these workers have byssinosis. Across all cells, the byssinosis rates vary from 0 to $28.7 \%$. Just to prove that there might be something here, let's obtain the average incidence rates according to the dustiness of the workplace:
. table (workplace) (race smokes) [fw=pop], statistic(mean prob) nototals

|  | Race |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Other <br> Smokes |  | White Smokes |  |
|  | No | Yes | No | Yes |
| Dustiness of workplace |  |  |  |  |
| Least | . 0107527 | . 0101523 | . 0081549 | . 0162774 |
| Less | . 02 | . 0081633 | . 0136612 | . 0143149 |
| Most | . 0820896 | . 1679105 | . 0833333 | . 2295082 |

Let's now fit the ANOVA model.
. anova prob workplace smokes race workplace\#smokes workplace\#race smokes\#race
( workplace\#smokes\#race [aweight=pop]
(sum of wgt is 5,419 )

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 65 \\ .025902 \end{array}$ | R-squared |  | $\begin{aligned} & 0.8300 \\ & 0.7948 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | . 17364654 | 11 | . 01578605 | 23.53 | 0.0000 |
| workplace | . 09762518 | 2 | . 04881259 | 72.76 | 0.0000 |
| smokes | . 01303081 | 1. | . 01303081 | 19.42 | 0.0001 |

| workplace\#smokes | . 01969034 | 2 | . 00984517 | 14.67 | 0.0000 |
| workplace\#race | . 00135252 | 2 | . 00067626 | 1.01 | 0.3718 |
| smokes\#race | . 00166287 | 1 | . 00166287 | 2.48 | 0.1214 |
| workplace\#smokes\#race | . 00095084 | 2 | . 00047542 | 0.71 | 0.4969 |
| Residual | . 03555777 | 53 | . 0006709 |  |  |
| Total | . 2092043 | 64 . | . 00326882 |  |  |

Of course, if we want to see the underlying regression, we could type regress.

Above, we examined simple means of the cells of workplace\#smokes\#race. Our ANOVA shows workplace, smokes, and their interaction as being the only significant factors in our model. We now examine the predictive marginal mean byssinosis rates for these terms.

```

Smoking combined with the most dusty workplace produces the highest byssinosis rates.

Ronald Aylmer Fisher (1890-1962) (Sir Ronald from 1952) studied mathematics at Cambridge. Even before he finished his studies, he had published on statistics. He worked as a statistician at Rothamsted Experimental Station (1919-1933), as professor of eugenics at University College London (1933-1943), as professor of genetics at Cambridge (1943-1957), and in retirement at the CSIRO Division of Mathematical Statistics in Adelaide. His many fundamental and applied contributions to statistics and genetics mark him as one of the greatest statisticians of all time, including original work on tests of significance, distribution theory, theory of estimation, fiducial inference, and design of experiments.

[^2]```
. use https://www.stata-press.com/data/r18/census2
(1980 Census data by state)
. summarize drate age region
```

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | :---: | :---: | :---: | ---: | ---: |
| drate | 50 | 84.3 | 13.07318 | 40 | 107 |
| age | 50 | 29.5 | 1.752549 | 24 | 35 |
| region | 50 | 2.66 | 1.061574 | 1 | 4 |

age is coded in integral years from 24 to 35 , and region is coded from 1 to 4 , with 1 standing for the Northeast, 2 for the North Central, 3 for the South, and 4 for the West.

When we examine the data more closely, we discover large differences in the deathrate across regions of the country:

| . tabulate region, summarize(drate) |  |  |  |
| ---: | ---: | :--- | ---: |
| Census <br> region | Summary of Deathrate <br> Mean <br> Std. dev. |  | Freq. |
| NE | 93.444444 | 7.0553368 | 9 |
| N Cntrl | 88.916667 | 5.5833899 | 12 |
| South | 88.3125 | 8.5457104 | 16 |
| West | 68.769231 | 13.342625 | 13 |
| Total | 84.3 | 13.073185 | 50 |

Naturally, we wonder if these differences might not be explained by differences in the median ages of the populations. To find out, we fit a regression model (via anova) of drate on region and age. In the anova example below, we treat age as a categorical variable.
. anova drate region age

|  | $\begin{aligned} \text { Number of obs } & = \\ \text { Root MSE } & = \end{aligned}$ | $\begin{array}{r} 50 \\ 6.7583 \end{array}$ | R -squared $=$ <br> Adj R -squared $=$ |  | $\begin{aligned} & 0.7927 \\ & 0.7328 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 6638.8653 | 11 | 603.53321 | 13.21 | 0.0000 |
| region | 1320.0097 | 3 | 440.00324 | 9.63 | 0.0001 |
| age | 2237.2494 | 8 | 279.65617 | 6.12 | 0.0000 |
| Residual | 1735.6347 | 38 | 45.674598 |  |  |
| Total | 8374.5 | 49 | 170.90816 |  |  |

We have the answer to our question: differences in median ages do not eliminate the differences in deathrates across the four regions. The ANOVA table summarizes the two terms in the model, region and age. The region term contains 3 degrees of freedom, and the age term contains 8 degrees of freedom. Both are significant at better than the $1 \%$ level.

The age term contains 8 degrees of freedom. Because we did not explicitly indicate that age was to be treated as a continuous variable, it was treated as categorical, meaning that unique coefficients were estimated for each level of age. The only clue of this labeling is that the number of degrees of freedom associated with the age term exceeds 1 . The labeling becomes more obvious if we review the regression coefficients:
. regress, baselevels

Although we started analyzing these data to explain the regional differences in deathrate, let's focus on the effect of age for a moment. In our first model, each level of age had a unique deathrate associated with it. For instance, the predicted deathrate in a north central state with a median age of 28 was

$$
0.44+12.66+68.37 \approx 81.47
$$

whereas the predicted deathrate from our current model is

$$
1.79+3.92 \times 28-28.60 \approx 82.95
$$

Our previous model had an $R^{2}$ of 0.7927 , whereas our current model has an $R^{2}$ of 0.7203 . This "small" loss of predictive power accompanies a gain of 7 degrees of freedom, so we suspect that the continuous-age model is as good as the discrete-age model.

## - Technical note

There is enough information in the two ANOVA tables to attach a statistical significance to our suspicion that the loss of predictive power is offset by the savings in degrees of freedom. Because the continuous-age model is nested within the discrete-age model, we can perform a standard Chow test. For those of us who know such formulas off the top of our heads, the $F$ statistic is

$$
\frac{(2342.41746-1735.63471) / 7}{45.6745977}=1.90
$$

There is, however, a better way.
We can find out whether our continuous model is as good as our discrete model by putting age in the model twice: once as a continuous variable and once as a categorical variable. The categorical variable will then measure deviations around the straight line implied by the continuous variable, and the $F$ test for the significance of the categorical variable will test whether those deviations are jointly zero.

| Model | 6638.8653 | 11 | 603.53321 | 13.21 | 0.0000 |
| region | 1320.0097 | 3 | 440.00324 | 9.63 | 0.0001 |
| age | 699.74137 | 1 | 699.74137 | 15.32 | 0.0004 |
| age | 606.78275 | 7 | 86.68325 | 1.90 | 0.0970 |
| Residual | 1735.6347 | 38 | 45.674598 |  |  |
| Total | 8374.5 | 49 | 170.90816 |  |  |

We find that the $F$ test for the significance of the (categorical) age variable is 1.90 , just as we calculated above. It is significant at the $9.7 \%$ level. If we hold to a $5 \%$ significance level, we cannot reject the null hypothesis that the effect of age is linear.
> Example 10: Interaction of continuous and categorical variables
In our census data, we still find significant differences across the regions after controlling for the median age of the population. We might now wonder whether the regional differences are differences in level-independent of age - or are instead differences in the regional effects of age. Just as we can interact categorical variables with other categorical variables, we can interact categorical variables with continuous variables.

| $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ |  | $\begin{array}{r} 50 \\ 7.24852 \end{array}$ | $\begin{array}{ll} \text { R-squared } & = \\ \text { Adj R-squared }= \end{array}$ |  | $\begin{aligned} & 0.7365 \\ & 0.6926 \end{aligned}$ |

| region\#age | 135.69116 | 3 | 45.230387 | 0.86 | 0.4689 |
| Residual | 2206.7263 | 425 | 52.541102 |  |  |
| Total | 8374.5 | $49 \quad 17$ | 170.90816 |  |  |

The region\#c. age term in our model measures the differences in slopes across the regions. We cannot reject the null hypothesis that there are no such differences. The region effect is now "insignificant". This status does not mean that there are no regional differences in deathrates because each test is a marginal or partial test. Here, with region\#c.age included in the model, region is being tested at the point where age is zero. Apart from this value not existing in the dataset, it is also a long way from the mean value of age, so the test of region at this point is meaningless (although it is valid if you acknowledge what is being tested).

To obtain a more sensible test of region, we can subtract the mean from the age variable and use this in the model.

```
. quietly summarize age
```

. generate mage $=$ age $-r$ (mean)
. anova drate region c.mage region\#c.mage

|  | Number of obs $=$ <br> Root MSE = | $\begin{array}{r} 50 \\ 7.24852 \end{array}$ | R -squared |  | $\begin{aligned} & 0.7365 \\ & 0.6926 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 6167.7737 | 7 | 881.11053 | 16.77 | 0.0000 |
| region | 1166.1473 | 3 | 388.71578 | 7.40 | 0.0004 |
| mage | 873.4256 | 1 | 873.4256 | 16.62 | 0.0002 |
| region\#mage | 135.69116 | 3 | 45.230387 | 0.86 | 0.4689 |
| Residual | 2206.7263 | 42 | 52.541102 |  |  |
| Total | 8374.5 | 49 | 170.90816 |  |  |

region is significant when tested at the mean of the age variable.

Remember that we can specify interactions by typing varname\#varname. We have seen examples of interacting categorical variables with categorical variables and, in the examples above, a categorical variable (region) with a continuous variable (age or mage).

We can also interact continuous variables with continuous variables. To include an age ${ }^{2}$ term in our model, we could type c.age\#c.age. If we also wanted to interact the categorical variable region with the age ${ }^{2}$ term, we could type region\#c.age\#c.age (or even c.age\#region\#c.age).

## Nested designs

In addition to specifying interaction terms, nested terms can also be specified in an ANOVA. A vertical bar is used to indicate nesting: A|B is read as A nested within B. A|B|C is read as A nested within $B$, which is nested within $C . A \mid B \# C$ is read as $A$ is nested within the interaction of $B$ and $C$. $A \# B \mid C$ is read as the interaction of $A$ and $B$, which is nested within $C$.

Different error terms can be specified for different parts of the model. The forward slash is used to indicate that the next term in the model is the error term for what precedes it. For instance, anova y $\mathrm{A} / \mathrm{B} \mid \mathrm{A}$ indicates that the $F$ test for A is to be tested by using the mean square from $\mathrm{B} \mid \mathrm{A}$ in the denominator. Error terms (terms following the slash) are generally not tested unless they are themselves followed by a slash. Residual error is the default error term.

For example, consider $A / B / C$, where $A, B$, and $C$ may be arbitrarily complex terms. Then, anova will report $A$ tested by $B$ and $B$ tested by $C$. If we add one more slash on the end to form $A / B / C /$, then anova will also report $C$ tested by the residual error.
> Example 11: Simple nested ANOVA
We have collected data from a manufacturer that is evaluating which of five different brands of machinery to buy to perform a particular function in an assembly line. Twenty assembly-line employees were selected at random for training on these machines, with four employees assigned to learn a particular machine. The output from each employee (operator) on the brand of machine for which he trained was measured during four trial periods. In this example, the operator is nested
within machine. Because of sickness and employee resignations, the final data are not balanced. The following table gives the mean output and sample size for each machine and operator combination.

```
. use https://www.stata-press.com/data/r18/machine, clear
(Machine data)
```

. table machine operator, statistic(mean output) statistic(freq)
> totals(machine) nformat (\%8.2f mean)

|  | Operator nested in machine |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
|  |  | 1 | 2 | 3 | 4 | Total

Assuming that operator is random (that is, we wish to infer to the larger population of possible operators) and machine is fixed (that is, only these five machines are of interest), the typical test for machine uses operator nested within machine as the error term. operator nested within machine can be tested by residual error. Our earlier warning concerning designs with either unplanned missing cells or unbalanced cell sizes, or both, also applies to interpreting the ANOVA results from this unbalanced nested example.

|  | $\begin{aligned} \text { Number of obs } & = \\ \text { Root MSE } & = \end{aligned}$ | $\begin{array}{r} 57 \\ 1.47089 \end{array}$ | R-squared = <br> Adj R -squared $=$ |  | $\begin{aligned} & 0.8661 \\ & 0.8077 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 545.82229 | 17 | 32.107193 | 14.84 | 0.0000 |
| machine | 430.98079 | 4 | 107.7452 | 13.82 | 0.0001 |
| operator\|machine | 101.3538 | 13 | 7.7964465 |  |  |
| operator\|machine | 101.3538 | 13 | 7.7964465 | 3.60 | 0.0009 |
| Residual | 84.376658 | 39 | 2.1635041 |  |  |
| Total | 630.19895 | 56 | 11.253553 |  |  |

operator|machine is preceded by a slash, indicating that it is the error term for the terms before it (here machine). operator|machine is also followed by a slash that indicates it should be tested with residual error. The output lists the operator|machine term twice, once as the error term for machine and again as a term tested by residual error. A line is placed in the ANOVA table to separate the two. In general, a dividing line is placed in the output to separate the terms into groups that are tested with the same error term. The overall model is tested by residual error and is separated from the rest of the table by a blank line at the top of the table.

The results indicate that the machines are not all equal and that there are significant differences between operators.

## > Example 12: ANOVA with multiple levels of nesting

Your company builds and operates sewage treatment facilities. You want to compare two particulate solutions during the particulate reduction step of the sewage treatment process. For each solution, two area managers are randomly selected to implement and oversee the change to the new treatment process in two of their randomly chosen facilities. Two workers at each of these facilities are trained to operate the new process. A measure of particulate reduction is recorded at various times during the month at each facility for each worker. The data are described below.

| ```. use https://www.stata-press.com/data/r18/sewage (Sewage treatment) . describe``` |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Contains data from https://www.stata-press.com/data/r18/sewage.dta |  |  |  |  |
| Observation |  | 64 |  | Sewage treatment |
| Variable |  | 5 |  | 9 May 2022 12:43 |
| Variable name | Storage type | $\begin{aligned} & \text { Display } \\ & \text { format } \end{aligned}$ | Value <br> label | Variable label |
| particulate | byte | $\% 9.0 \mathrm{~g}$ |  | Particulate reduction |
| solution | byte | \%9.0g |  | 2 particulate solutions |
| manager | byte | \%9.0g |  | 2 managers per solution |
| facility | byte | \%9.0g |  | 2 facilities per manager |
| worker | byte | \%9.0g |  | 2 workers per facility |

You want to determine if the two particulate solutions provide significantly different particulate reduction. You would also like to know if manager, facility, and worker are significant effects. solution is a fixed factor, whereas manager, facility, and worker are random factors.

In the following anova command, we use abbreviations for the variable names, which can sometimes make long ANOVA model statements easier to read.
. anova particulate $s / m|s / f| m|s / w| f|m| s /, d r o p e m p t y c e l l s$

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $12.74$ | R-squared = <br> Adj R-squared = |  | $\begin{aligned} & 0.6338 \\ & 0.5194 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 13493.609 | 15 | 899.57396 | 5.54 | 0.0000 |
| solution | 7203.7656 | 1 | 7203.7656 | 17.19 | 0.0536 |
| manager\|solution | 838.28125 | 2 | 419.14063 |  |  |
| manager\|solution | 838.28125 | 2 | 419.14063 | 0.55 | 0.6166 |
| facility\|manager| solution | 3064.9375 | 4 | 766.23438 |  |  |
| facility\|manager| |  |  |  |  |  |
| solution | 3064.9375 | 4 | 766.23438 | 2.57 | 0.1193 |
| worker\|facilityl |  |  |  |  |  |
| manager\|solution | 2386.625 | 8 | 298.32813 |  |  |
| worker\|facilityl |  |  |  |  |  |
| manager\|solution | 2386.625 | 8 | 298.32813 | 1.84 | 0.0931 |
| Residual | 7796.25 | 48 | 162.42188 |  |  |
| Total | 21289.859 | 63 | 337.93428 |  |  |

While solution is not declared significant at the $5 \%$ significance level, it is near enough to that threshold to warrant further investigation (see example 3 in $[\mathrm{R}]$ anova postestimation for a continuation of the analysis of these data).

## - Technical note

Why did we use the dropemptycells option with the previous anova? By default, Stata retains empty cells when building the design matrix and currently treats $\mid$ and \# the same in how it determines the possible number of cells. Retaining empty cells in an ANOVA with nested terms can cause your design matrix to become too large. In example 12, there are $1024=2 \times 4 \times 8 \times 16$ cells that are considered possible for the worker|facility|manager|solution term because the worker, facility, and manager variables are uniquely numbered. With the dropemptycells option, the worker|facility|manager|solution term requires just 16 columns in the design matrix (corresponding to the 16 unique workers).

Why did we not use the dropemptycells option in example 11, where operator is nested in machine? If you look at the table presented at the beginning of that example, you will see that operator is compactly instead of uniquely numbered (you need both operator number and machine number to determine the operator). Here the dropemptycells option would have only reduced our design matrix from 26 columns down to 24 columns (because there were only 3 operators instead of 4 for machines 3 and 5).

We suggest that you specify dropemptycells when there are nested terms in your ANOVA. You could also use the set emptycells drop command to accomplish the same thing; see [R] set.

## Mixed designs

An ANOVA can consist of both nested and crossed terms. A split-plot ANOVA design provides an example.

## > Example 13: Split-plot ANOVA

Two reading programs and three skill-enhancement techniques are under investigation. Ten classes of first-grade students were randomly assigned so that five classes were taught with one reading program and another five classes were taught with the other. The 30 students in each class were divided into six groups with 5 students each. Within each class, the six groups were divided randomly so that each of the three skill-enhancement techniques was taught to two of the groups within each class. At the end of the school year, a reading assessment test was administered to all the students. In this split-plot ANOVA, the whole-plot treatment is the two reading programs, and the split-plot treatment is the three skill-enhancement techniques.

Sorted by:
In this split-plot ANOVA, the error term for program is class nested within program. The error term for skill and the program by skill interaction is the class by skill interaction nested within program. Other terms are also involved in the model and can be seen below.

Our anova command is too long to fit on one line of this manual. Where we have chosen to break the command into multiple lines is arbitrary. If we were typing this command into Stata, we would just type along and let Stata automatically wrap across lines, as necessary.

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 300 \\ 14.6268 \end{array}$ | R-squared = <br> Adj R-squared $=$ |  | $\begin{aligned} & 0.3738 \\ & 0.2199 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 30656.517 | 59 | 519.60198 | 2.43 | 0.0000 |
| program | 4493.07 | 1 | 4493.07 | 8.73 | 0.0183 |
| class\|program | 4116.6133 | 8 | 514.57667 |  |  |
| skill | 1122.6467 | 2 | 561.32333 | 1.54 | 0.2450 |
| program\#skill | 5694.62 | 2 | 2847.31 | 7.80 | 0.0043 |
| class\#skill\|program | 5841.4667 | 16 | 365.09167 |  |  |
| class\#skill\|program group|class\#skill| | 5841.4667 | 16 | 365.09167 | 1.17 | 0.3463 |
| program | 9388.1 | 30 | 312.93667 |  |  |
| group\|class\#skill| program | 9388.1 | 30 | 312.93667 | 1.46 | 0.0636 |
| Residual | 51346.4 | 240 | 213.94333 |  |  |
| Total | 82002.917 | 299 | 274.25725 |  |  |

The program\#skill term is significant, as is the program term. Let's look at the predictive margins for these two terms and at a marginsplot for the first term.

```
. margins, within(program skill)
Predictive margins Number of obs = 300
Expression: Linear prediction, predict()
Within: program skill
Empty cells: reweight
```

|  | Margin | lta-metho std. err. | t | $P>\|t\|$ | [95\% con | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| program\#skill |  |  |  |  |  |  |
| 11 | 68.16 | 2.068542 | 32.95 | 0.000 | 64.08518 | 72.23482 |
| 12 | 52.86 | 2.068542 | 25.55 | 0.000 | 48.78518 | 56.93482 |
| 13 | 61.54 | 2.068542 | 29.75 | 0.000 | 57.46518 | 65.61482 |
| 21 | 50.7 | 2.068542 | 24.51 | 0.000 | 46.62518 | 54.77482 |
| 22 | 56.54 | 2.068542 | 27.33 | 0.000 | 52.46518 | 60.61482 |
| 23 | 52.1 | 2.068542 | 25.19 | 0.000 | 48.02518 | 56.17482 |

```
. marginsplot, plot2opts(m(D)) plot3opts(m(T))
Variables that uniquely identify margins: program skill
```

| Predictive margins |  |  |  |  | Number of obs $=300$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Expression: Linear prediction, predict() <br> Within: program <br> Empty cells: reweight | ```Linear prediction, predict() program reweight``` |  |  |  |  |  |
|  | Margin | lta-method <br> std. err | t | $P>\|t\|$ | [95\% con | interval] |
| program |  |  |  |  |  |  |
| 1 | 60.85333 | 1.194273 | 50.95 | 0.000 | 58.50074 | 63.20593 |
| 2 | 53.11333 | 1.194273 | 44.47 | 0.000 | 50.76074 | 55.46593 |

Because our ANOVA involves nested terms, we used the within() option of margins; see [R] margins.
skill 2 produces a low score when combined with program 1 and a high score when combined with program 2, demonstrating the interaction between the reading program and the skill-enhancement technique. You might conclude that the first reading program and the first skill-enhancement technique perform best when combined. However, notice the overlapping confidence interval for the first reading program and the third skill-enhancement technique.

## - Technical note

There are several valid ways to write complicated anova terms. In the reading experiment example (example 13), we had a term grouplclass\#skill|program. This term can be read as group nested within both class and skill and further nested within program. You can also write this term as grouplclass\#skill\#program or grouplprogram\#class\#skill or grouplskill\#class|program, etc. All variations will produce the same result. Some people prefer having only one ' $\mid$ ' in a term and would use grouplclass\#skill\#program, which is read as group nested within class, skill, and program.

Gertrude Mary Cox (1900-1978) was born on a farm near Dayton, Iowa. Initially intending to become superintendent of an orphanage, she enrolled at Iowa State College. There she majored in mathematics and attained the college's first Master's degree in statistics. After working on her PhD in psychological statistics for two years at the University of California-Berkeley, she decided to go back to Iowa State to work with George W. Snedecor. There she pursued her interest in and taught a course in design of experiments. That work led to her collaboration with W. G. Cochran, which produced a classic text. In 1940, when Snedecor shared with her his list of men he was nominating to head the statistics department at North Carolina State College, she wanted to know why she had not been included. He added her name, she won the position, and she built an outstanding department at North Carolina State. Cox retired early so she could work at the Research Triangle Institute in North Carolina. She consulted widely, served as editor of Biometrics, and was elected to the National Academy of Sciences.

## Latin-square designs

You can use anova to analyze a Latin-square design. Consider the following example, published in Snedecor and Cochran (1989).

## > Example 14: Latin-square ANOVA

Data from a Latin-square design are as follows:

| Row | Column 1 | Column 2 | Column 3 | Column 4 | Column 5 |
| ---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $257(\mathrm{~B})$ | $230(\mathrm{E})$ | $279(\mathrm{~A})$ | $287(\mathrm{C})$ | $202(\mathrm{D})$ |
| 2 | $245(\mathrm{D})$ | $283(\mathrm{~A})$ | $245(\mathrm{E})$ | $280(\mathrm{~B})$ | $260(\mathrm{C})$ |
| 3 | $182(\mathrm{E})$ | $252(\mathrm{~B})$ | $280(\mathrm{C})$ | $246(\mathrm{D})$ | $250(\mathrm{~A})$ |
| 4 | $203(\mathrm{~A})$ | $204(\mathrm{C})$ | $227(\mathrm{D})$ | $193(\mathrm{E})$ | $259(\mathrm{~B})$ |
| 5 | $231(\mathrm{C})$ | $271(\mathrm{D})$ | $266(\mathrm{~B})$ | $334(\mathrm{~A})$ | $338(\mathrm{E})$ |

In Stata, the data might appear as follows:

```
. use https://www.stata-press.com/data/r18/latinsq
```

. list

| row | $c 1$ | $c 2$ | $c 3$ | $c 4$ | $c 5$ |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 257 | 230 | 279 | 287 | 202 |
| 2 | 245 | 283 | 245 | 280 | 260 |
| 3 | 182 | 252 | 280 | 246 | 250 |
| 4 | 203 | 204 | 227 | 193 | 259 |
| 5 | 231 | 271 | 266 | 334 | 338 |

Before anova can be used on these data, the data must be organized so that the outcome measurement is in one column. reshape is inadequate for this task because there is information about the treatments in the sequence of these observations. pkshape is designed to reshape this type of data; see [R] pkshape.
. pkshape row row c1-c5, order(beacd daebc ebcda acdeb cdbae)

These methods will work with any type of Latin-square design, including those with replicated measurements. For more information, see $[R] \mathbf{p k},[R]$ pkcross, and $[R]$ pkshape.

## Repeated-measures ANOVA

One approach for analyzing repeated-measures data is to use multivariate ANOVA (MANOVA); see [MV] manova. In this approach, the data are placed in wide form (see [D] reshape), and the repeated measures enter the MANOVA as dependent variables.

A second approach for analyzing repeated measures is to use anova. However, one of the underlying assumptions for the $F$ tests in ANOVA is independence of observations. In a repeated-measures design, this assumption is almost certainly violated. In a repeated-measures ANOVA, the subjects (or whatever the experimental units are called) are observed for each level of one or more of the other categorical variables in the model. These variables are called the repeated-measure variables. Observations from the same subject are likely to be correlated, though this is only a problem if the observations violate compound symmetry or the sphericity condition.

The approach used in repeated-measures ANOVA to correct for violation of compound symmetry or sphericity is to apply correction to the degrees of freedom of the $F$ test for terms in the model that involve repeated measures. This correction factor, $\epsilon$, lies between the reciprocal of the degrees of freedom for the repeated term and 1. Box (1954) provided the pioneering work in this area. Milliken and Johnson (2009) refer to the lower bound of this correction factor as Box's conservative correction factor. Winer, Brown, and Michels (1991) call it simply the conservative correction factor.

Geisser and Greenhouse (1958) provide an estimate for the correction factor called the GreenhouseGeisser $\epsilon$. This value is estimated from the data. Huynh and Feldt (1976) show that the GreenhouseGeisser $\epsilon$ tends to be conservatively biased. They provide a revised correction factor called the Huynh-Feldt $\epsilon$. When the Huynh-Feldt $\epsilon$ exceeds 1 , it is set to 1 . Thus, there is a natural ordering for these correction factors:

$$
\text { Box's conservative } \epsilon \leq \text { Greenhouse-Geisser } \epsilon \leq \text { Huynh-Feldt } \epsilon \leq 1
$$

A correction factor of 1 is the same as no correction.
anova with the repeated() option computes these correction factors and displays the revised test results in a table that follows the standard ANOVA table. In the resulting table, H-F stands for Huynh-Feldt, G-G stands for Greenhouse-Geisser, and Box stands for Box's conservative $\epsilon$.
$>$ Example 15: Repeated-measures ANOVA
This example is taken from table 4.3 of Winer, Brown, and Michels (1991). The reaction time for five subjects each tested with four drugs was recorded in the variable score. Here is a table of the data (see [P] tabdisp if you are unfamiliar with tabdisp):

```
. use https://www.stata-press.com/data/r18/t43, clear
(T4.3 -- Winer, Brown, Michels)
. tabdisp person drug, cellvar(score)
```

|  | Drug <br> Person |  |  |  |
| ---: | ---: | ---: | ---: | ---: |
|  | 1 | 2 | 3 | 4 |
| 1 | 30 | 28 | 16 | 34 |
| 2 | 14 | 18 | 10 | 22 |
| 3 | 24 | 20 | 18 | 30 |
| 4 | 38 | 34 | 20 | 44 |
| 5 | 26 | 28 | 14 | 30 |

drug is the repeated variable in this simple repeated-measures ANOVA example. The ANOVA is specified as follows:
. anova score person drug, repeated(drug)

Here the Huynh-Feldt $\epsilon$ is 1.0789 , which is larger than 1 . It is reset to 1 , which is the same as making no adjustment to the standard test computed in the main ANOVA table. The Greenhouse-Geisser $\epsilon$ is 0.6049 , and its associated $p$-value is computed from an $F$ ratio of 24.76 using $1.8147(=3 \epsilon)$ and $7.2588(=12 \epsilon)$ degrees of freedom. Box's conservative $\epsilon$ is set equal to the reciprocal of the degrees of freedom for the repeated term. Here it is $1 / 3$, so Box's conservative test is computed using 1 and 4 degrees of freedom for the observed $F$ ratio of 24.76.

Even for Box's conservative $\epsilon$, drug is significant with a $p$-value of 0.0076 . The following table gives the predictive marginal mean score (that is, response time) for each of the four drugs:

| . margins drug | Number of obs $=20$ |
| :--- | :--- |
| Predictive margins |  |
| Expression: Linear prediction, predict() |  |

|  | MarginDelta-method <br> std. err. | t | $\mathrm{P}>\mid \mathrm{tI}$ | [95\% conf. interval] |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| drug |  |  |  |  |  |  |
| 1 | 26.4 | 1.371131 | 19.25 | 0.000 | 23.41256 | 29.38744 |
| 2 | 25.6 | 1.371131 | 18.67 | 0.000 | 22.61256 | 28.58744 |
| 3 | 15.6 | 1.371131 | 11.38 | 0.000 | 12.61256 | 18.58744 |
| 4 | 32 | 1.371131 | 23.34 | 0.000 | 29.01256 | 34.98744 |

The ANOVA table for this example provides an $F$ test for person, but you should ignore it. An appropriate test for person would require replication (that is, multiple measurements for person and drug combinations). Also, without replication there is no test available for investigating the interaction between person and drug.

## > Example 16: Repeated-measures ANOVA with nesting

Table 7.7 of Winer, Brown, and Michels (1991) provides another repeated-measures ANOVA example. There are four dial shapes and two methods for calibrating dials. Subjects are nested within calibration method, and an accuracy score is obtained. The data are shown below.

```
. use https://www.stata-press.com/data/r18/t77
(T7.7 -- Winer, Brown, Michels)
. tabdisp shape subject calib, cell(score)
```

| 4 dial shapes | 2 methods for calibrating dials and Subject nested in calib |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |
|  | 1 | 2 | 3 | 1 | 2 | 3 |
| 1 | 0 | 3 | 4 | 4 | 5 | 7 |
| 2 | 0 | 1 | 3 | 2 | 4 | 5 |
| 3 | 5 | 5 | 6 | 7 | 6 | 8 |
| 4 | 3 | 4 | 2 | 8 | 6 | 9 |

The calibration method and dial shapes are fixed factors, whereas subjects are random. The appropriate test for calibration method uses the nested subject term as the error term. Both the dial shape and the interaction between dial shape and calibration method are tested with the dial shape by subject interaction nested within calibration method. Here we drop this term from the anova command, and it becomes residual error. The dial shape is the repeated variable because each subject is tested with all four dial shapes. Here is the anova command that produces the desired results:

The repeated-measure $\epsilon$ corrections are applied to any terms that are tested in the main ANOVA table and have the repeated variable in the term. These $\epsilon$ corrections are given in a table below the main ANOVA table. Here the repeated-measures tests for shape and calib\#shape are presented.

Calibration method is significant, as is dial shape. The interaction between calibration method and dial shape is not significant. The repeated-measure $\epsilon$ corrections do not change these conclusions, but they do change the significance level for the tests on shape and calib\#shape. Here, though, unlike in the example 15, the Huynh-Feldt $\epsilon$ is less than 1 .

Here are the predictive marginal mean scores for calibration method and dial shapes. Because the interaction was not significant, we request only the calib and shape predictive margins.

| Predictive margins |  |  |  |  | Number of obs $=24$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Expression: Linear prediction, predict() <br> Within: calib <br> Empty cells: reweight |  |  |  |  |  |  |
|  | Margin | lta-method std. err | t | $P>\|t\|$ | [95\% conf | interval] |
| calib |  |  |  |  |  |  |
| 1 | 3 | . 3209506 | 9.35 | 0.000 | 2.300709 | 3.699291 |
| 2 | 5.916667 | . 3209506 | 18.43 | 0.000 | 5.217375 | 6.615958 |
| . margins, within(shape) |  |  |  |  |  |  |
| Predictive margins Number of obs $=24$ |  |  |  |  |  |  |
| Expression: Linear prediction, predict() Within: shape |  |  |  |  |  |  |
| Empty cells: reweight |  |  |  |  |  |  |

|  | Delta-method <br> std. err. |  |  |  | t | $\mathrm{P}>\|\mathrm{t}\|$ |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Margin | [95\% conf. interval] |  |  |  |  |
| shape |  |  |  |  |  |  |
| 1 | 3.833333 | .4538926 | 8.45 | 0.000 | 2.844386 | 4.82228 |
| 2 | 2.5 | .4538926 | 5.51 | 0.000 | 1.511053 | 3.488947 |
| 3 | 6.166667 | .4538926 | 13.59 | 0.000 | 5.17772 | 7.155614 |
| 4 | 5.333333 | .4538926 | 11.75 | 0.000 | 4.344386 | 6.32228 |

## Technical note

The computation of the Greenhouse-Geisser and Huynh-Feldt epsilons in a repeated-measures ANOVA requires the number of levels and degrees of freedom for the between-subjects error term, as well as a value computed from a pooled covariance matrix. The observations are grouped based on all but the lowest-level variable in the between-subjects error term. The covariance over the repeated variables is computed for each resulting group, and then these covariance matrices are pooled. The dimension of the pooled covariance matrix is the number of levels of the repeated variable (or combination of levels for multiple repeated variables). In example 16, there are four levels of the repeated variable (shape), so the resulting covariance matrix is $4 \times 4$.

The anova command automatically attempts to determine the between-subjects error term and the lowest-level variable in the between-subjects error term to group the observations for computation of the pooled covariance matrix. anova issues an error message indicating that the bse() or bseunit () option is required when anova cannot determine them. You may override the default selections of anova by specifying the bse(), bseunit(), or grouping() option. The term specified in the bse() option must be a term in the ANOVA model.

The default selection for the between-subjects error term (the bse() option) is the interaction of the nonrepeated categorical variables in the ANOVA model. The first variable listed in the between-subjects error term is automatically selected as the lowest-level variable in the between-subjects error term but can be overridden with the bseunit (varname) option. varname is often a term, such as subject or subsample within subject, and is most often listed first in the term because of the nesting notation of ANOVA. This term makes sense in most repeated-measures ANOVA designs when the terms of the model are written in standard form. For instance, in example 16, there were three categorical variables (subject, calib, and shape), with shape being the repeated variable. Here anova looked for a term involving only subject and calib to determine the between-subjects error term. It found subject|calib as the term with six levels and 4 degrees of freedom. anova then picked subject as the default for the bseunit () option (the lowest variable in the between-subjects error term) because it was listed first in the term.

The grouping of observations proceeds, based on the different combinations of values of the variables in the between-subjects error term, excluding the lowest level variable (as found by default or as specified with the bseunit() option). You may specify the grouping() option to change the default grouping used in computing the pooled covariance matrix.

The between-subjects error term, number of levels, degrees of freedom, lowest variable in the term, and grouping information are presented after the main ANOVA table and before the rest of the repeated-measures output.
> Example 17: Repeated-measures ANOVA with two repeated variables
Data with two repeated variables are given in table 7.13 of Winer, Brown, and Michels (1991). The accuracy scores of subjects making adjustments to three dials during three different periods are recorded. Three subjects are exposed to a certain noise background level, whereas a different set of three subjects is exposed to a different noise background level. Here is a table of accuracy scores for the noise, subject, period, and dial variables:

```
. use https://www.stata-press.com/data/r18/t713
(T7.13 -- Winer, Brown, Michels)
. tabdisp subject dial period, by(noise) cell(score) stubwidth(11)
```

| Noise background and Subject nested in noise | 1 | $\begin{gathered} 10 \\ 1 \\ 2 \end{gathered}$ | nute <br> 3 |  | $\begin{gathered} \mathrm{ods} \\ 2 \\ 2 \end{gathered}$ | T 3 | $\frac{\mathrm{d}}{1}$ | $\begin{gathered} 3 \\ 2 \end{gathered}$ | 3 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 |  |  |  |  |  |  |  |  |  |
| 1 | 45 | 53 | 60 | 40 | 52 | 57 | 28 | 37 | 46 |
| 2 | 35 | 41 | 50 | 30 | 37 | 47 | 25 | 32 | 41 |
| 3 | 60 | 65 | 75 | 58 | 54 | 70 | 40 | 47 | 50 |
| 2 |  |  |  |  |  |  |  |  |  |
| 1 | 50 | 48 | 61 | 25 | 34 | 51 | 16 | 23 | 35 |
| 2 | 42 | 45 | 55 | 30 | 37 | 43 | 22 | 27 | 37 |
| 3 | 56 | 60 | 77 | 40 | 39 | 57 | 31 | 29 | 46 |

noise, period, and dial are fixed, whereas subject is random. Both period and dial are repeated variables. The ANOVA for this example is specified next.
. anova score noise / subject|noise period noise\#period /
> period\#subject|noise dial noise\#dial /
> dial\#subject|noise period\#dial noise\#period\#dial, repeated(period dial)

| Residual | 16 |  |  |  |  |  |  |

For each repeated variable and for each combination of interactions of repeated variables, there are different $\epsilon$ correction values. The anova command produces tables for each applicable combination.

The two most significant factors in this model appear to be dial and period. The noise by period interaction may also be significant, depending on the correction factor you use. Below is a table of predictive margins for the accuracy score for dial, period, and noise by period.

```
. margins, within(dial)
Predictive margins Number of obs = 54
Expression: Linear prediction, predict()
Within: dial
Empty cells: reweight
```

|  | Delta-method |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Margin | std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| dial |  |  |  |  |  |  |
| 1 | 37.38889 | .6643478 | 56.28 | 0.000 | 35.98053 | 38.79724 |
| 2 | 42.22222 | .6643478 | 63.55 | 0.000 | 40.81387 | 43.63058 |
| 3 | 53.22222 | .6643478 | 80.11 | 0.000 | 51.81387 | 54.63058 |

```
. margins, within(period)
Predictive margins Number of obs = 54
Expression: Linear prediction, predict()
Within: period
Empty cells: reweight
```

|  | Delta-method |  |  |  |  |  |
| ---: | ---: | :---: | :---: | :---: | :---: | :---: |
|  | Margin | std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| period |  |  |  |  |  |  |
| 1 | 54.33333 | .6643478 | 81.78 | 0.000 | 52.92498 | 55.74169 |
| 2 | 44.5 | .6643478 | 66.98 | 0.000 | 43.09165 | 45.90835 |
| 3 | 34 | .6643478 | 51.18 | 0.000 | 32.59165 | 35.40835 |

| . margins, within(noise period) |
| :--- |
| Predictive margins |
| Expression: <br> Within: <br> Empty cells:Linear prediction, predict() <br> noise period <br> reweight |

Dial shape 3 produces the highest score, and scores decrease over the periods.

Example 17 had two repeated-measurement variables. Up to four repeated-measurement variables may be specified in the anova command.

## Title

anova postestimation - Postestimation tools for anova

| Postestimation commands | predict | margins | test |
| :--- | :--- | :--- | :--- |
| Remarks and examples | References | Also see |  |

## Postestimation commands

The following postestimation commands are of special interest after anova:

| Command | Description |
| :--- | :--- |
| dfbeta | DFBETA influence statistics |
| estat hettest | tests for heteroskedasticity |
| estat imtest | information matrix test |
| estat ovtest | Ramsey regression specification-error test for omitted variables |
| estat szroeter | Szroeter's rank test for heteroskedasticity |
| estat vif | variance inflation factors for the independent variables |
| estat esize | $\eta^{2}$ and $\omega^{2}$ effect sizes |
| rvfplot | residual-versus-fitted plot |
| avplot | added-variable plot |
| avplots | all added-variables plots in one image |
| cprplot | component-plus-residual plot |
| acprplot | augmented component-plus-residual plot |
| rvpplot | residual-versus-predictor plot |
| lvr2plot | leverage-versus-squared-residual plot |

The following standard postestimation commands are also available:

| Command | Description |
| :--- | :--- |
| contrast | contrasts and ANOVA-style joint tests of estimates <br> estat ic |
| Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian in- |  |
| formation criteria (AIC, CAIC, AICc, and BIC) |  |
| estat vce | variance-covariance matrix of the estimators (VCE) <br> estimates <br> etable |
| cataloging estimation results |  |
| table of estimation results |  |
| hausman | dynamic forecasts and simulations |
| lincom | Hausman's specification test |
| point estimates, standard errors, testing, and inference for linear combinations of |  |
| linktest | link test for model specification |
| lrtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects <br> graph the results from margins (profile plots, interaction plots, etc.) |
| marginsplot | point estimates, standard errors, testing, and inference for nonlinear combinations <br> of coefficients |
| nlcom | predictions and their SEs, leverage statistics, distance statistics, etc. <br> point estimates, standard errors, testing, and inference for generalized predictions |
| predict | pairwise comparisons of estimates |
| predictnl | seemingly unrelated estimation |
| pwcompare | Wald tests of simple and composite linear hypotheses |
| suest | Wald tests of nonlinear hypotheses |

## predict

predict after anova follows the same syntax as predict after regress and can provide predictions, residuals, standardized residuals, Studentized residuals, the standard error of the residuals, the standard error of the prediction, the diagonal elements of the projection (hat) matrix, and Cook's $D$. See $[R]$ regress postestimation for details.

## margins

margins after anova follows the same syntax as margins after regress. See [R] regress postestimation for details.

## test

## Description for test

In addition to the standard syntax of test (see [R] test), test after anova has three additionally allowed syntaxes; see below. test performs Wald tests of expressions involving the coefficients of the underlying regression model. Simple and composite linear hypotheses are possible.

## Menu for test

Statistics $>$ Linear models and related $>$ ANOVA/MANOVA $>$ Test linear hypotheses after anova

## Syntax for test

| test, test(matname) $[\underline{\text { mtest }[(o p t)}]$ matvlc(matname) $]$ | syntax a |
| :--- | :--- |
| test, showorder | syntax b |
| $\underline{\text { test }[\text { term }[\text { term } . . .]][/ \operatorname{term}[\text { term } . . .]][\text {, symbolic }]}$ | syntax c |

syntax a test expression involving the coefficients of the underlying regression model; you provide information as a matrix
syntax b show underlying order of design matrix, which is useful when constructing matname argument of the test () option
syntax c test effects and show symbolic forms

## Options for test

test (matname) is required with syntax a of test. The rows of matname specify linear combinations of the underlying design matrix of the ANOVA that are to be jointly tested. The columns correspond to the underlying design matrix (including the constant if it has not been suppressed). The column and row names of matname are ignored.

A listing of the constraints imposed by the test () option is presented before the table containing the tests. You should examine this table to verify that you have applied the linear combinations you desired. Typing test, showorder allows you to examine the ordering of the columns for the design matrix from the ANOVA.
mtest $[(o p t)]$ specifies that tests are performed for each condition separately. opt specifies the method for adjusting $p$-values for multiple testing. Valid values for opt are

| bonferroni | Bonferroni's method |
| :--- | :--- |
| holm | Holm's method |
| šidak | Šidák's method |
| noadjust | no adjustment is to be made |

Specifying mtest with no argument is equivalent to mtest (noadjust).
matvlc(matname), a programmer's option, saves the variance-covariance matrix of the linear combinations involved in the suite of tests. For the test $\mathbf{L b}=\mathbf{c}$, what is returned in matname is $\mathbf{L} V \mathbf{L}^{\prime}$, where $V$ is the estimated variance-covariance matrix of $\mathbf{b}$.
showorder causes test to list the definition of each column in the design matrix. showorder is not allowed with any other option.
symbolic requests the symbolic form of the test rather than the test statistic. When this option is specified with no terms (test, symbolic), the symbolic form of the estimable functions is displayed.

## Remarks and examples

Remarks are presented under the following headings:

```
Testing effects
Obtaining symbolic forms
Testing coefficients and contrasts of margins
Video example
```

See examples $4,7,8,13,15,16$, and 17 in $[R]$ anova for examples that use the margins command.

## Testing effects

After fitting a model using anova, you can test for the significance of effects in the ANOVA table, as well as for effects that are not reported in the ANOVA table, by using the test or contrast command. You follow test or contrast by the list of effects that you wish to test. By default, these commands use the residual mean squared error in the denominator of the $F$ ratio. You can specify other error terms by using the slash notation, just as you would with anova. See [R] contrast for details on this command.

## > Example 1: Testing effects

Recall our byssinosis example (example 8) in [R] anova:

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 65 \\ .025902 \end{array}$ | $\begin{array}{ll} \text { R-squared } & = \\ \text { Adj R-squared }= \end{array}$ |  | $\begin{aligned} & 0.8300 \\ & 0.7948 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | . 17364654 | 11 | . 01578605 | 23.53 | 0.0000 |
| workplace | . 09762518 | 2. | . 04881259 | 72.76 | 0.0000 |
| smokes | . 01303081 | 1. | . 01303081 | 19.42 | 0.0001 |
| race | . 00109472 | 1 | . 00109472 | 1.63 | 0.2070 |
| workplace\#smokes | . 01969034 | 2 | . 00984517 | 14.67 | 0.0000 |
| workplace\#race | . 00135252 | 2 | . 00067626 | 1.01 | 0.3718 |
| smokes\#race | . 00166287 | 1 | . 00166287 | 2.48 | 0.1214 |
| workplace\#smokes\#race | . 00095084 | 2 | . 00047542 | 0.71 | 0.4969 |
| Residual | . 03555777 | 53 | . 0006709 |  |  |
| Total | . 2092043 | 64. | . 00326882 |  |  |

We can easily obtain a test on a particular term from the ANOVA table. Here are two examples:

```
. test smokes
```

| Source | Partial SS | df | MS | F | Prob>F |
| ---: | ---: | ---: | ---: | ---: | ---: |
| smokes | .01303081 | 1 | .01303081 | 19.42 | 0.0001 |
| Residual | .03555777 | 53 | .0006709 |  |  |

. test smokes\#race

| Source | Partial SS | df | MS | F | Prob>F |
| ---: | ---: | ---: | :---: | :---: | :---: |
| smokes\#race | .00166287 | 1 | .00166287 | 2.48 | 0.1214 |
| Residual | .03555777 | 53 | .0006709 |  |  |

Both of these tests use residual error by default and agree with the ANOVA table produced earlier.
We could have performed these same tests with contrast:

```
. contrast smokes
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | P>F |
| ---: | ---: | ---: | ---: |
| smokes | 1 | 19.42 | 0.0001 |
| Denominator | 53 |  |  |

. contrast smokes\#race
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :--- | :---: | :---: | ---: |
| smokes\#race | 1 | 2.48 | 0.1214 |
| Denominator | 53 |  |  |

## - Technical note

After anova, you can use the '/' syntax in test or contrast to perform tests with a variety of non $-\sigma^{2} \mathbf{I}$ error structures. However, in most unbalanced models, the mean squares are not independent and do not have equal expectations under the null hypothesis. Also, be warned that you assume responsibility for the validity of the test statistic.

## Example 2: Testing effects with different error terms

We return to the nested ANOVA example (example 11) in [R] anova, where five brands of machinery were compared in an assembly line. We can obtain appropriate tests for the nested terms using test, even if we had run the anova command without initially indicating the proper error terms.

```
. use https://www.stata-press.com/data/r18/machine
(Machine data)
. anova output machine / operator|machine /
\begin{tabular}{|c|c|c|c|c|c|}
\hline & \[
\begin{array}{ll}
\text { Number of obs } & = \\
\text { Root MSE } & =
\end{array}
\] & \[
\begin{array}{r}
57 \\
1.47089
\end{array}
\] & \multicolumn{2}{|l|}{\begin{tabular}{l}
R -squared \(=\) \\
Adj R-squared \(=\)
\end{tabular}} & \[
\begin{aligned}
& 0.8661 \\
& 0.8077
\end{aligned}
\] \\
\hline Source & Partial SS & df & MS & F & Prob>F \\
\hline Model & 545.82229 & 17 & 32.107193 & 14.84 & 0.0000 \\
\hline machine & 430.98079 & 4 & 107.7452 & 13.82 & 0.0001 \\
\hline operator|machine & 101.3538 & 13 & 7.7964465 & & \\
\hline operator|machine & 101.3538 & 13 & 7.7964465 & 3.60 & 0.0009 \\
\hline Residual & 84.376658 & 39 & 2.1635041 & & \\
\hline Total & 630.19895 & 56 & 11.253553 & & \\
\hline
\end{tabular}
```

In this ANOVA table, machine is tested with residual error. With this particular nested design, the appropriate error term for testing machine is operator nested within machine, which is easily obtained from test.

```
. test machine / operator|machine
\begin{tabular}{r|rrrrr} 
Source & Partial SS & df & MS & F & Prob>F \\
\hline machine & 430.98079 & 4 & 107.7452 & 13.82 & 0.0001 \\
operator machine & 101.3538 & 13 & 7.7964465 & &
\end{tabular}
```

This result from test matches what we obtained from our anova command.

## Example 3: Pooling terms when testing effects

The other nested ANOVA example (example 12) in [R] anova was based on the sewage data. The ANOVA table is presented here again. As before, we will use abbreviations of variable names in typing the commands.

In practice, it is often beneficial to pool nonsignificant nested terms to increase the power of tests on remaining terms. One rule of thumb is to allow the pooling of a term whose $p$-value is larger than 0.25 . In this sewage example, the $p$-value for the test of manager is 0.6166 . This value indicates that the manager effect is negligible and might be ignored. Currently, solution is tested by manager|solution, which has only 2 degrees of freedom. If we pool the manager and facility terms and use this pooled estimate as the error term for solution, we would have a term with 6 degrees of freedom.

Below are two tests: a test of solution with the pooled manager and facility terms and a test of this pooled term by worker.

| Source | Partial SS | df | MS | F | Prob>F |
| :---: | :---: | :---: | :---: | :---: | :---: |
| solution manager\|solution facility|manager| solution | 7203.7656 3903.2188 | 1 6 | 7203.7656 650.53646 | 11.07 | 0.0159 |
| . test $\mathrm{m}\|\mathrm{s} \mathrm{f}\| \mathrm{m}\|\mathrm{s} / \mathrm{w}\| \mathrm{f} \mid \mathrm{m}$ <br> Source | Partial SS | df | MS | F | Prob>F |
| manager\|solution facility|manager| solution worker|facility|manager| solution | 3903.2188 2386.625 | 6 8 | $\begin{aligned} & 650.53646 \\ & 298.32813 \end{aligned}$ | 2.18 | 0.1520 |

In the first test, we included two terms after the forward slash ( $\mathrm{m} \mid \mathrm{s}$ and $\mathrm{f}|\mathrm{m}| \mathrm{s}$ ). test after anova allows multiple terms both before and after the slash. The terms before the slash are combined and are then tested by the combined terms that follow the slash (or residual error if no slash is present).

The $p$-value for solution using the pooled term is 0.0159 . Originally, it was 0.0536 . The increase in the power of the test is due to the increase in degrees of freedom for the pooled error term.

We can get identical results if we drop manager from the anova model. (This dataset has unique numbers for each facility so that there is no confusion of facilities when manager is dropped.)

This output agrees with our earlier test results.

In the following example, two terms from the anova are jointly tested (pooled).

## > Example 4: Obtaining overall significance of a term using contrast

In example 10 of $[R]$ anova, we fit the model anova drate region c.mage region\#c.mage. Now, we use the contrast command to test for the overall significance of region.

```
. contrast region region#c.mage, overall
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | $d f$ | $F$ | $P>F$ |
| ---: | :---: | :---: | ---: |
| region | 3 | 7.40 | 0.0004 |
| region\#c.mage | 3 | 0.86 | 0.4689 |
| Overall | 6 | 5.65 | 0.0002 |
| Denominator | 42 |  |  |

The overall $F$ statistic associated with the region and region\#c.mage terms is 5.65 , and it is significant at the $0.02 \%$ level.

In the ANOVA output, the region term, by itself, had a sum of squares of 1166.15 , which, based on 3 degrees of freedom, yielded an $F$ statistic of 7.40 and a significance level of 0.0004 . This is the same test that is reported by contrast in the row labeled region. Likewise, the test from the ANOVA output for the region\#c.mage term is reproduced in the second row of the contrast output.

## Obtaining symbolic forms

test can produce the symbolic form of the estimable functions and symbolic forms for particular tests.

## > Example 5: Symbolic form of the estimable functions

After fitting an ANOVA model, we type test, symbolic to obtain the symbolic form of the estimable functions. For instance, returning to our blood pressure data introduced in example 4 of $[R]$ anova, let's begin by reestimating systolic on drug, disease, and drug\#disease:

To obtain the symbolic form of the estimable functions, type

```
. test, symbolic
drug
    -(r2+r3+r4-r0)
    r2
    3 r3
disease
    -(r6+r7-r0)
        r6
        r7
drug#disease
    1 1 -(r2+r3+r4+r6+r7-r12-r13-r15-r16-r18-r19-r0)
    1 2 r6 - (r12+r15+r18)
    1 3 r7 - (r13+r16+r19)
    2 1 r2 - (r12+r13)
    2 2 r12
    2 3 r13
    3 1 r3 - (r15+r16)
    3 2 r15
    3 3 r16
    4 1 r4 - (r18+r19)
    4 r r18
    4 3 r19
_cons r0
```

> Example 6: Symbolic form for a particular test
To obtain the symbolic form for a particular test, we type test term [term ...], symbolic. For instance, the symbolic form for the test of the main effect of drug is

| $\begin{aligned} & \text {. tes } \\ & \text { drug } \end{aligned}$ | 1 | $-(r 2+r 3+r 4)$ |
| :---: | :---: | :---: |
|  | 2 | r2 |
|  | 3 | r3 |
|  | 4 | r4 |
| disease |  |  |
|  | 1 | 0 |
|  | 2 | 0 |
|  | 3 | 0 |
| drug\#disease |  |  |
| 1 | 1 | $-1 / 3$ (r2+r3+r4) |
| 1 | 2 | $-1 / 3$ (r2+r3+r4) |
| 1 | 3 | $-1 / 3$ (r2+r3+r4) |
| 2 | 1 | 1/3 r2 |
| 2 | 2 | 1/3 r2 |
| 2 | 3 | 1/3 r2 |
| 3 | 1 | 1/3 r3 |
| 3 | 2 | 1/3 r3 |
| 3 | 3 | 1/3 r3 |
| 4 | 1 | 1/3 r4 |
| 4 | 2 | 1/3 r4 |
| 4 | 3 | 1/3 r4 |
| _cons |  | 0 |

If we omit the symbolic option, we instead see the result of the test:

```
. test drug
```

| Source | Partial SS | df | MS | F | Prob>F |
| ---: | ---: | ---: | :---: | :---: | :---: |
| drug | 2997.4719 | 3 | 999.15729 | 9.05 | 0.0001 |
| Residual | 5080.8167 | 46 | 110.45254 |  |  |

## Testing coefficients and contrasts of margins

The test command allows you to perform tests directly on the coefficients of the underlying regression model. For instance, the coefficient on the third drug and the second disease is referred to as 3.drug\#2.disease. This could also be written as i3.drug\#i2.disease, or _b[3.drug\#2.disease], or even _coef[i3.drug\#i2.disease]; see [U] 13.5 Accessing coefficients and standard errors.
> Example 7: Testing linear combinations of coefficients
Let's begin by testing whether the coefficient on the third drug is equal to the coefficient on the fourth drug in our blood pressure data. We have already fit the model anova systolic drug\#\#disease (equivalent to anova systolic drug disease drug\#disease), and you can see the results of that estimation in example 5. Even though we have performed many tasks since we fit the model, Stata still remembers, and we can perform tests at any time.

```
. test 3.drug = 4.drug
( 1) 3.drug - 4.drug = 0
    F( 1, 46) = 0.13
        Prob > F = 0.7234
```

We find that the two coefficients are not significantly different, at least at any significance level smaller than $73 \%$.

For more complex tests, the contrast command often provides a more concise way to specify the test we are interested in and prevents us from having to write the tests in terms of the regression coefficients. With contrast, we instead specify our tests in terms of differences in the marginal means for the levels of a particular factor. For example, if we want to compare the third and fourth drugs, we can test the difference in the mean impact on systolic blood pressure separately for each disease using the @ operator. We also use the reverse adjacent operator, ar., to compare the fourth level of drug with the previous level.

```
. contrast ar4.drug@disease
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | :---: | :---: |
| drug@disease |  |  |  |
| (4 vs 3) 1 | 1 | 0.13 | 0.7234 |
| (4 vs 3) 2 | 1 | 1.76 | 0.1917 |
| (4 vs 3) 3 | 1 | 0.65 | 0.4230 |
| Joint | 3 | 0.85 | 0.4761 |
| Denominator | 46 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | :--- | :--- | :--- |
| drug@disease |  |  |  |  |
| $(4$ vs 3) 1 | -2.733333 | 7.675156 | -18.18262 | 12.71595 |
| $(4$ vs 3) 2 | 8.433333 | 6.363903 | -4.376539 | 21.24321 |
| $(4$ vs 3) 3 | 5.7 | 7.050081 | -8.491077 | 19.89108 |

None of the individual contrasts shows significant differences between the third drug and the fourth drug. Likewise, the overall $F$ statistic is 0.85 , which is hardly significant. We cannot reject the hypothesis that the third drug has the same effect as the fourth drug.

## - Technical note

Alternatively, we could have specified these tests based on the coefficients of the underlying regression model using the test command. We would have needed to perform tests on the coefficients for drug and for the coefficients on drug interacted with disease to test for differences in the means mentioned above. To do this, we start with our previous test command:

```
. test 3.drug = 4.drug
```

Notice that the $F$ statistic for this test is equivalent to the test labeled ( 4 vs 3 ) 1 in the contrast output. Let's now add the constraint that the coefficient on the third drug interacted with the third disease is equal to the coefficient on the fourth drug, again interacted with the third disease. We do that by typing the new constraint and adding the accumulate option:

```
. test 3.drug#3.disease = 4.drug#3.disease, accumulate
( 1) 3.drug - 4.drug = 0
( 2) 3.drug#3.disease - 4.drug#3.disease = 0
    F( 2, 46) = 0.39
        Prob > F = 0.6791
```

So far, our test includes the equality of the two drug coefficients, along with the equality of the two drug coefficients when interacted with the third disease. Now, we add two more equations, one for each of the remaining two diseases:

```
. test 3.drug#2.disease = 4.drug#2.disease, accumulate
( 1) 3.drug - 4.drug = 0
( 2) 3.drug#3.disease - 4.drug#3.disease = 0
( 3) 3.drug#2.disease - 4.drug#2.disease = 0
    F( 3, 46) = 0.85
    Prob > F = 0.4761
. test 3.drug#1.disease = 4.drug#1.disease, accumulate
( 1) 3.drug - 4.drug = 0
( 2) 3.drug#3.disease - 4.drug#3.disease = 0
( 3) 3.drug#2.disease - 4.drug#2.disease = 0
(4) 3o.drug#1b.disease - 4o.drug#1b.disease = 0
    Constraint 4 dropped
    F( 3, 46) = 0.85
        Prob > F = 0.4761
```

The overall $F$ statistic reproduces the one from the joint test in the contrast output.
You may notice that we also got the message "Constraint 4 dropped". For the technically inclined, this constraint was unnecessary, given the normalization of the model. If we specify all the constraints involved in our test or use contrast, we need not worry about the normalization because Stata handles this automatically.

The test () option of test provides another alternative for testing coefficients. Instead of spelling out each coefficient involved in the test, a matrix representing the test provides the needed information. test, showorder shows the order of the terms in the ANOVA corresponding to the order of the columns for the matrix argument of test ().

## > Example 8: Another way to test linear combinations of coefficients

We repeat the last test of example 7 above with the test () option. First, we view the definition and order of the columns underlying the ANOVA performed on the systolic data.

```
. test, showorder
Order of columns in the design matrix
    (drug==1)
    (drug==2)
    (drug==3)
    (drug==4)
    (disease==1)
    (disease==2)
    (disease==3)
    (drug==1)*(disease==1)
    (drug==1)*(disease==2)
    (drug==1)*(disease==3)
    (drug==2)*(disease==1)
    (drug==2)*(disease==2)
    (drug==2)*(disease==3)
    (drug==3)*(disease==1)
    (drug==3)*(disease==2)
    (drug==3)*(disease==3)
    (drug==4)*(disease==1)
    (drug==4)*(disease==2)
    (drug==4)*(disease==3)
    _cons
```

Columns 1-4 correspond to the four levels of drug. Columns 5-7 correspond to the three levels of disease. Columns $8-19$ correspond to the interaction of drug and disease. The last column corresponds to _cons, the constant in the model.

We construct the matrix $\operatorname{dr} 3 \mathrm{vs} 4$ with the same four constraints as the last test shown in example 7 and then use the test (dr3vs4) option to perform the test.

```
. matrix dr3vs4 = (0,0,1,-1, 0,0,0, 0,0,0,0,0,0,0,0,0, 0, 0, 0, 0 \
> 0,0,0,0,0,0,0, 0,0,0,0,0,0,0,0,1,0,0,-1,0\
    0,0,0, 0, 0,0,0, 0,0,0,0,0,0,0,1,0, 0,-1, 0, 0\
    0,0,0, 0, 0,0,0, 0,0,0,0,0,0,1,0,0,-1, 0, 0, 0)
. test, test(dr3vs4)
( 1) 3.drug - 4.drug = 0
( 2) 3.drug#3.disease - 4.drug#3.disease = 0
( 3) 3.drug#2.disease - 4.drug#2.disease = 0
( 4) 3o.drug#1b.disease - 4o.drug#1b.disease = 0
    Constraint 4 dropped
    F( 3, 46) = 0.85
        Prob > F = 0.4761
```

Here the effort involved with spelling out the coefficients is similar to that of constructing a matrix and using it in the test () option. When the test involving coefficients is more complicated, the test () option may be more convenient than specifying the coefficients directly in test. However, as previously demonstrated, contrast may provide an even simpler method for testing the same hypothesis.

After fitting an ANOVA model, various contrasts (1-degree-of-freedom tests comparing different levels of a categorical variable) are often of interest. contrast can perform each 1-degree-of-freedom test in addition to the combined test, even in cases in which the contrasts do not correspond to one of the contrast operators.

## > Example 9: Testing particular contrasts of interest

Rencher and Schaalje (2008) illustrate 1-degree-of-freedom contrasts for an ANOVA comparing the net weight of cans filled by five machines (labeled A-E). The data were originally obtained from Ostle and Mensing (1975). Rencher and Schaalje use a cell-means ANOVA model approach for this problem. We could do the same by using the noconstant option of anova; see [R] anova. Instead, we obtain the same results by using the standard overparameterized ANOVA approach (that is, we keep the constant in the model).

```
. use https://www.stata-press.com/data/r18/canfill
(Can fill data)
. list, sepby(machine)
```

|  | machine | weight |
| :---: | :---: | :---: |
| 1. | A | 11.95 |
| 2. | A | 12.00 |
| 3. | A | 12.25 |
| 4. | A | 12.10 |
| 5. | B | 12.18 |
| 6. | B | 12.11 |
| 7. | C | 12.16 |
| 8. | C | 12.15 |
| 9. | C | 12.08 |
| 10. | D | 12.25 |
| 11. | D | 12.30 |
| 12. | D | 12.10 |
| 13. | E | 12.10 |
| 14. | E | 12.04 |
| 15. | E | 12.02 |
| 16. | E | 12.02 |

. anova weight machine

| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | . 05942699 | 4 | . 01485675 | 1.93 | 0.1757 |
| machine | . 05942699 | 4 | . 01485675 | 1.93 | 0.1757 |
| Residual | . 0847167 | 11 | . 00770152 |  |  |
| Total | . 14414369 | 15 | . 00960958 |  |  |

The four 1-degree-of-freedom tests of interest among the five machines are $A$ and $D$ versus $B, C$, and E ; B and E versus C ; A versus D ; and B versus E . We can specify these tests as user-defined contrasts by placing the corresponding contrast coefficients into positions related to the five levels of machine as described in User-defined contrasts of [R] contrast.

```
. contrast {machine 3-2 -2 3-2}
```

```
> {machine 1 0 0 0 -1 0}
> {machine 0 1 0 0 -1}, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| machine |  |  |  |
| $(1)$ | 1 | 0.75 | 0.4055 |
| $(2)$ | 1 | 0.31 | 0.5916 |

| (4) | 1 | 1.73 | 0.2150 |
| Joint | 4 | 1.93 | 0.1757 |
| Denominator | 11 |  |  |

contrast produces a 1-degree-of-freedom test for each of the specified contrasts as well as a joint test. We included the noeffects option so that the table displaying the values of the individual contrasts with their confidence intervals was suppressed.

The significance values above are not adjusted for multiple comparisons. We could have produced the Bonferroni-adjusted significance values by using the mcompare(bonferroni) option.

```
. contrast {machine 3-2 -2 3-2}
> {machine 0 1 -2 0 1}
> {machine 1 0 0 -1 0}
> {machine 0 1 0 0 -1}, mcompare(bonferroni) noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | Bonferroni |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | P>F | $\mathrm{P}>\mathrm{F}$ |
| machine |  |  |  |  |
| (1) | 1 | 0.75 | 0.4055 | 1.0000 |
| (2) | 1 | 0.31 | 0.5916 | 1.0000 |
| (3) | 1 | 4.47 | 0.0582 | 0.2329 |
| (4) | 1 | 1.73 | 0.2150 | 0.8601 |
| Joint | 4 | 1.93 | 0.1757 |  |
| Denominator | 11 |  |  |  |

Note: Bonferroni-adjusted p-values are reported for tests
on individual contrasts only.

## $>$ Example 10: Linear and quadratic contrasts

Here there are two factors, A and B, each with three levels. The levels are quantitative so that linear and quadratic contrasts are of interest.
. use https://www.stata-press.com/data/r18/twowaytrend
. anova Y A B A\#B

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 36 \\ 2.6736 \end{array}$ | R-squared = <br> Adj R-squared = |  | $\begin{aligned} & 0.9304 \\ & 0.9097 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 2578.5556 | 8 | 322.31944 | 45.09 | 0.0000 |
| A | 2026.7222 | 2 | 1013.3611 | 141.77 | 0.0000 |
| B | 383.72222 | 2 | 191.86111 | 26.84 | 0.0000 |
| A\#B | 168.11111 | 4 | 42.027778 | 5.88 | 0.0015 |
| Residual | 193 | 27 | 7.1481481 |  |  |
| Total | 2771.5556 | 35 | 79.187302 |  |  |

We can use the p. contrast operator to obtain the 1-degree-of-freedom tests for the linear and quadratic effects of $A$ and $B$.

```
. contrast p.A p.B, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | ---: | ---: |
| A |  |  |  |
| (linear) | 1 | 212.65 | 0.0000 |
| (quadratic) | 1 | 70.88 | 0.0000 |
| Joint | 2 | 141.77 | 0.0000 |
| B |  |  |  |
| (linear) | 1 | 26.17 | 0.0000 |
| (quadratic) | 1 | 27.51 | 0.0000 |
| Joint | 2 | 26.84 | 0.0000 |
| Denominator | 27 |  |  |

All the above tests appear to be significant. In addition to presenting the 1-degree-of-freedom tests, the combined tests for A and B are produced and agree with the original ANOVA results.

Now, we explore the interaction between A and B.

```
. contrast p.A#p1.B, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | $d f$ | $F$ | $P>F$ |
| ---: | ---: | ---: | ---: |
| A\#B |  |  |  |
| (linear) (linear) | 1 | 17.71 | 0.0003 |
| (quadratic) (linear) | 1 | 0.07 | 0.7893 |
| Joint | 2 | 8.89 | 0.0011 |
| Denominator | 27 |  |  |

The 2-degrees-of-freedom test of the interaction of A with the linear components of B is significant at the 0.0011 level. But, when we examine the two 1-degree-of-freedom tests that compose this result,
the significance is due to the linear A by linear B contrast (significance level of 0.0003). A significance value of 0.7893 for the quadratic A by linear B indicates that this factor is not significant for these data.

```
. contrast p.A#p2.B, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| (linear) (quadratic) |  |  |  |
| (quadratic) (quadratic) | 1 | 2.80 | 0.1058 |
|  | Joint | 1 | 2.94 |
|  | 2 | 2.87 | 0.0979 |
|  | Denominator | 27 |  |

The test of A with the quadratic components of B does not fall below the 0.05 significance level.

## Description

areg fits linear regression absorbing categorical factors. areg is designed for datasets with categorical variables that have many groups, but the number of groups for each variable does not increase with the sample size. See the xtreg, fe command in [XT] xtreg for an estimator that handles the case in which one categorical variable (often a panel identifier) has a number of groups that increases with the sample size; additional categorical variables with fixed group sizes may also be included.

## Quick start

Linear regression of y on x , absorbing indicator variables for the levels of cvar
areg $\mathrm{y} x, \operatorname{absorb(cvar)}$
Same as above, but add categorical variable a
areg y x i.a, absorb(cvar)
Same as above, but with cluster-robust standard errors
areg $y \mathrm{x}$ i.a, absorb(cvar) vce(cluster cvar2)
Linear regression of y on x , absorbing indicator variables for the levels of cvar1 and cvar2 (StataNow)
$\operatorname{areg} \mathrm{y} x, \operatorname{absorb}(c v a r 1 \mathrm{cvar} 2)$

## Menu

areg depvar [indepvars][if][in][weight], absorb(...) [options]
options
Description
Model

* absorb (varname) categorical variable to be absorbed
${ }^{+*}$ absorb (varlist $[$, method $]$ ) specify categorical variables to be absorbed
${ }^{+}$noabsorbtest suppress the $F$ test of absorbed indicators
SE/Robust
vce (vcetype) vcetype may be ols, robust, cluster clustvarlist, bootstrap, jackknife, or hc2 $[$ clustvar $]$

Reporting
level (\#)
clustertable
display_options
set confidence level; default is level (95)
display table of multiway cluster combinations
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

Optimization
$+\dagger$ tolerance (\#)
$+\dagger_{\text {iterate }}(\#)$
$+\dagger$ nolog
coeflegend
convergence tolerance for maximum absolute difference; default is tolerance ( $1 \mathrm{e}-8$ )
maximum number of iterations for alternating projection method (APM); default is iterate(50)
suppress the APM iteration $\log$
display legend instead of statistics
${ }^{+}$These features are part of StataNow.
*absorb() is required.
$\dagger_{\text {Ignored if only one absorbed variable is specified. }}$
indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bootstrap, by, collect, fp, jackknife, mi estimate, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.
vce (bootstrap) and vce (jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
aweights are not allowed with the jackknife prefix; see $[R]$ jackknife.
aweights, fweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

absorb (varlist $[$, method $]$ ) is part of StataNow. It specifies the categorical variables to be absorbed. The results are adjusted as if indicator variables for each level of each variable in varlist were included in the regression. absorb() is required.
When more than one categorical variable is absorbed, an APM iterative algorithm is used to project the depvar and indepvars to absorb these variables. method specifies the APM and is one of halperin or cimmino.
halperin, the default, uses the product of the projection matrices.
cimmino uses the mean of the projection matrices.
The two methods typically perform similarly. See Stammann (2018) for details.
method is ignored if only one absorbed variable is specified.
noabsorbtest is part of StataNow. It prevents computation of the $F$ test that all coefficients on indicators for absorbed variables are jointly zero. Computation of this test requires an iterative search. If the $F$ test is of no interest, you may specify noabsorbtest and save computational time.

SE/Robust
vce (vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (ols), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvarlist), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
vce(ols), the default, uses the standard variance estimator for ordinary least-squares regression.
vce(cluster clustvarlist) specifies that standard errors allow for intragroup correlation within groups defined by one or more variables in clustvarlist, relaxing the usual requirement that the observations be independent. For example, vce(cluster clustvar1) produces clusterrobust standard errors that allow for observations that are independent across groups defined by clustvar1 but not necessarily independent within groups. You could also type vce (cluster clustvar1 clustvar2 ... clusterp) to account for correlation within groups formed by $p$ variables (multiway clustering).
areg also allows the following:
vce (hc2 [clustvar] [, dfadjust]) specifies an alternative bias correction for the robust variance calculation. In the unclustered case, vce(robust) uses $\widehat{\sigma}_{j}^{2}=\{n /(n-k)\} u_{j}^{2}$ as an estimate of the variance of the $j$ th observation, where $n$ is the number of observations, $k$ is the number of regressors, $u_{j}$ is the calculated residual, and $n /(n-k)$ is included to improve the overall estimate's small-sample properties.
vce (hc2) instead uses $u_{j}^{2} /\left(1-h_{j j}\right)$ as the observation's variance estimate, where $h_{j j}$ is the diagonal element of the hat (projection) matrix. This estimate is unbiased if the model really is homoskedastic. vce (hc2) tends to produce slightly more conservative confidence intervals. vce (hc2 clustvar) produces estimates that allow for intragroup correlation within groups defined by clustvar. dfadjust computes the Bell and McCaffrey (2002) adjusted degrees of freedom based on clustvar. Note that dfadjust does not affect multiple-imputation results when the command is used with mi estimate. See Methods and formulas in [R] regress for a description of the computation when clustvar is specified.
vce(hc2 clustvar) is not allowed when multiple variables are absorbed.
level (\#); see [R] Estimation options.
clustertable displays a table reporting cluster combinations and the number of clusters per combination. This option is available only when vce (cluster clustvarlist) is specified with more than one variable in clustvarlist to compute multiway cluster-robust standard errors.
display_options: noci, nopvalues, dfci, dfpvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat(\% firt), pformat (\% fint), sformat (\%fmt), and nolstretch; see [R] Estimation options.
dfci specifies that parameter degrees of freedom and confidence intervals be reported in the coefficient table.
dfpvalues specifies that parameter degrees of freedom and $p$-values be reported in the coefficient table.

Optimization
tolerance (\#) is part of StataNow. It specifies the limit for the maximum absolute difference between iterations for the projected depvar and indepvars. The default is tolerance(1e-8).
iterate (\#) is part of StataNow. It specifies the maximum number of iterations for the APM. The default is iterate (50).
nolog is part of StataNow. It specifies that no APM iterative log be displayed.
The following option is available with areg but is not shown in the dialog box: coeflegend; see [R] Estimation options.

## Remarks and examples

Suppose that we have a linear regression model that includes among predictor variables indicators for the levels of a high-dimensional categorical variable $C$. For instance, the levels of $C$ could represent counties, neighborhoods, or streets. We could write the model as

$$
\mathbf{y}=\mathbf{X} \boldsymbol{\beta}+\mathbf{d}_{1} \gamma_{1}+\mathbf{d}_{2} \gamma_{2}+\cdots+\mathbf{d}_{m} \gamma_{m}+\boldsymbol{\epsilon}
$$

Alternatively, if there are $N$ observations and $m$ categories of variable $C$, we could write this as

$$
\mathbf{y}=\mathbf{X} \boldsymbol{\beta}+\mathbf{D} \gamma+\epsilon
$$

where $\mathbf{D}$ is an $N \times m$ indicator matrix for the categories of $C$ and

$$
\mathbf{D}=\left(\begin{array}{llll}
\mathbf{d}_{1} & \mathbf{d}_{2} & \ldots & \mathbf{d}_{m}
\end{array}\right) \gamma=\left(\begin{array}{c}
\gamma_{1} \\
\gamma_{2} \\
\vdots \\
\gamma_{m}
\end{array}\right)
$$

Each $\mathbf{d}_{a}$ is a column vector, the indicator variable for category $a$ of variable $C$.
One option would be to fit the model with regress,
but this may be computationally expensive when the dimension, $m$, is very large. Moreover, you may not be interested in the estimates of $\gamma$, but you want the remaining results to be adjusted for the inclusion of $C$ in the model.
areg provides a faster way of obtaining estimates of $\boldsymbol{\beta}$ —but not the $\gamma_{i}$ 's—in these cases. The effects of the $C$ variable are said to be absorbed.

## Example 1

So that we can compare the results produced by areg with Stata's other regression commands, we will fit a model in which $m$ is small. areg's real use, however, is when $m$ is large.

In our automobile data, we have a variable called rep78 that is coded $1,2,3,4$, and 5 , where 1 means poor and 5 means excellent. Let's assume that we wish to fit a regression of mpg on weight, gear_ratio, and rep78 (parameterized as a set of indicators).

```
. use https://www.stata-press.com/data/r18/auto2
(1978 automobile data)
. regress mpg weight gear_ratio b5.rep78
```

| ---: | :---: | :---: | :---: | :---: | ---: | ---: |
| weight | -.0051031 | .0009206 | -5.54 | 0.000 | -.0069433 | -.003263 |
| gear_ratio | .901478 | 1.565552 | 0.58 | 0.567 | -2.228015 | 4.030971 |
| _cons | 34.05889 | 7.056383 | 4.83 | 0.000 | 19.95338 | 48.1644 |
| F test of absorbed indicators: $F(4,62)=1.117$ |  | Prob $>\mathrm{F}=0.356$ |  |  |  |  |

Both regress and areg display the same $R^{2}$ values, root mean squared error, and-for weight and gear_ratio-the same parameter estimates, standard errors, $t$ statistics, significance levels, and confidence intervals. areg, however, does not report the coefficients for rep78, and, in fact, they are not even calculated. This computational trick makes the problem manageable when $m$ is large. areg reports a test that the coefficients associated with rep78 are jointly zero. Here this test has a significance level of $35.6 \%$. This $F$ test for rep78 is the same that we would obtain after regress if we were to specify test 1. rep78 2.rep78 3.rep78 4.rep78; see $[R]$ test.

The model $F$ tests reported by regress and areg also differ. The regress command reports a test that all coefficients except that of the constant are equal to zero; thus, the indicators are included in this test. The areg output shows a test that all coefficients excluding the indicators and the constant are equal to zero. This is the same test that can be obtained after regress by typing test weight gear_ratio.

## - Technical note

areg is designed for datasets with many groups, but not a number that grows with the sample size. Consider two different samples from the US population. In the first sample, we have 10,000 individuals and we want to include an indicator for each of the 50 states, whereas in the second sample we have 3 observations on each of 10,000 individuals and we want to include an indicator for each individual. areg was designed for datasets similar to the first sample in which we have a fixed number of groups, the 50 states. In the second sample, the number of groups, which is the number of individuals, grows as we include more individuals in the sample. For an estimator designed to handle the case in which the number of groups grows with the sample size, see the xtreg, fe command in $[\mathrm{XT}]$ xtreg.

Although the point estimates produced by areg and xtreg, fe are the same, the estimated VCEs differ when vce (cluster clustvarlist) is specified because the commands make different assumptions about whether the number of groups increases with the sample size.

## - Technical note

The intercept reported by areg deserves some explanation because, given $m$ mutually exclusive and exhaustive indicators, it is arbitrary. areg identifies the model by choosing the intercept that makes the prediction calculated at the means of the independent variables equal to the mean of the dependent variable: $\overline{\mathbf{y}}=\overline{\mathbf{x}} \widehat{\boldsymbol{\beta}}$.

| Variable | Obs | Mean | Std. dev. | Min | Max |
| :---: | :---: | :---: | :---: | :---: | :---: |
| mpg | 69 | 21.28986 | 5.866408 | 12 | 41 |
| yhat | 69 | 21.28986 | 4.383224 | 11.58643 | 28.07367 |

We had to include if rep78 < . in our summarize command because we have missing values in our data. areg automatically dropped those missing values (as it should) in forming the estimates, but predict with the xb option will make predictions for cases with missing rep78 because it does not know that rep78 is really part of our model.

These predicted values do not include the absorbed effects (that is, the $\mathbf{d}_{i} \gamma_{i}$ ). For predicted values that include these effects, use the xbd option of predict (see [R] areg postestimation) or see [XT] xtreg.

## > Example 2

areg, vce (robust) is a Huberized version of areg; see [P] _robust. Just as areg is equivalent to using regress with indicators, areg, vce (robust) is equivalent to using regress, vce (robust) with indicators. You can use areg, vce (robust) when you expect heteroskedastic or nonnormal errors. areg, vce(robust), like ordinary regression, assumes that the observations are independent, unless the vce (cluster clustvarlist) or vce(hc2 clustvar) option is specified. If the vce (cluster clustvarlist) or vce(hc2 clustvar) option is specified, this independence assumption is relaxed and only the clusters identified by equal values of clustvarlist or clustvar are assumed to be independent.

Assume that we were to collect data by randomly sampling 10,000 doctors (from 100 hospitals) and then sampling 10 patients of each doctor, yielding a total dataset of 100,000 patients in a cluster sample. If in some regression we wished to include effects of the hospitals to which the doctors belonged, we would want to include an indicator variable for each hospital, adding 100 variables to our model. areg could fit this model by

```
. areg depvar patient_vars, absorb(hospital) vce(cluster doctor)
```

## Stored results

areg stores the following in e() :

In addition to the above, the following is stored in r() :
$r(t a b l e) \quad$ matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

With one absorbed variable, areg begins by recalculating depvar and indepvars to have mean 0 within the groups specified by absorb(). The overall mean of each variable is then added back in. The adjusted depvar is then regressed on the adjusted indepvars with regress, yielding the coefficient estimates. This is a direct application of the Frisch-Waugh-Lovell theorem (see Hansen [2022, 82]). The degrees of freedom of the variance-covariance matrix of the coefficients is then adjusted to account for the absorbed variables - this calculation yields the same results (up to numerical roundoff error) as if the matrix had been calculated directly by the formulas given in $[R]$ regress.

With multiple absorbed variables in StataNow, an APM with a conjugate gradient acceleration technique is used to adjust the depvar and indepvars (Hernández-Ramos, Escalante, and Raydan 2011). Two projection methods are available: Halperin (the default) and Cimmino. You can specify which to use with the halperin or cimmino suboption within the absorb() option. We describe both methods below.

Suppose we have $h$ categorical variables, $C_{1}, \ldots, C_{h}$, that we would like to include as controls in our regression. For variable $C_{k}$, let $m_{k}$ be its number of levels and $\mathbf{d}_{k(a)}$ be its $N \times 1$ indicator vector for category $a$ of $C_{k}$. Let $\mathbf{D}_{k}$ denote the $N \times m_{k}$ matrix of indicators for variable $C_{k}$ :

$$
\mathbf{D}_{k}=\left(\begin{array}{llll}
\mathbf{d}_{k(1)} & \mathbf{d}_{k(2)} & \ldots & \mathbf{d}_{k(m)}
\end{array}\right)
$$

The orthonormal projection matrix for $C_{k}$ is therefore given by $\mathbf{P}_{k}=\mathbf{D}_{k}\left(\mathbf{D}_{k}^{\prime} \mathbf{D}_{k}\right)^{-1} \mathbf{D}_{k}^{\prime}$. Let $\mathbf{y}$ be the $N \times 1$ vector with the values of the dependent variable in the sample. Similarly, let $\mathbf{X}$ be the matrix with the values of the covariates. Thus, the product $\overline{\mathbf{y}}_{k}=\mathbf{P}_{k} \mathbf{y}$ is the projection of the dependent variable onto the column space of $\mathbf{D}_{k}$. That is, $\overline{\mathbf{y}}_{k}$ is the $N \times 1$ vector containing the (repeated) means of $y_{i}$ for each level of $C_{k}$, in the order that these levels appear in the sample. The same projection is applied to the columns of covariate matrix $\mathbf{X}$.

The Halperin algorithm first sets $\widetilde{\mathbf{y}}_{0}^{(1)}=\mathbf{y}$ and loops over the $h$ absorbed variables computing projection residuals $\widetilde{\mathbf{y}}_{k}^{(1)}=\left(\mathbf{I}-\mathbf{P}_{\mathbf{k}}\right) \widetilde{\mathbf{y}}_{k-1}^{(1)}$, for $k=1, \ldots, h$. Then, it repeats the loop with $\widetilde{\mathbf{y}}_{0}^{(j+1)}=$ $\widetilde{\mathbf{y}}_{h}^{(j)}$ until convergence at $j=\jmath$. Convergence is declared when $\left|\widetilde{\mathbf{y}}_{h}^{(\jmath)}-\widetilde{\mathbf{y}}_{0}^{(\jmath)}\right|$ is less than the specified tolerance, where the matrix norm $|\cdot|$ is defined as the largest entry in absolute value. The same computations are applied to the columns of covariate matrix $\mathbf{X}$. On convergence, the overall mean $\bar{y}$ is added to $\widetilde{\mathbf{y}}_{h}^{(\jmath)}$, and the vector of means $\overline{\mathbf{x}}$ is added to the columns of $\widetilde{\mathbf{X}}_{h}^{(\jmath)}$.

The Cimmino algorithm first sets $\widetilde{\mathbf{y}}^{(0)}=\mathbf{y}$ and then iteratively computes

$$
\widetilde{\mathbf{y}}^{(j+1)}=\left(\mathbf{I}-\frac{1}{h} \sum_{k=1}^{h} \mathbf{P}_{k}\right) \widetilde{\mathbf{y}}^{(j)}
$$

until convergence at $j+1=\jmath$. It then repeats the process for covariance matrix $\mathbf{X}$ and adds the overall means, $\overline{\mathbf{y}}$ and $\overline{\mathbf{x}}$, to $\widetilde{\mathbf{y}}^{(\jmath)}$ and to the columns of $\widetilde{\mathbf{X}}^{(\jmath)}$, respectively.

Efficient computation of the projection $\mathbf{P y}$ can be done in Mata without generating the $N \times N$ matrix $\mathbf{P}$ directly (see function panelsum(), for instance).
areg with vce(robust) or vce(cluster clustvarlist) with only one variable specified in clustvarlist works similarly, calling _robust after regress to produce the Huber/White/sandwich estimator of the variance or its clustered version. See [P] _robust, particularly Introduction and Methods and formulas. For $p$-way clustering, vce(cluster clustvarl [clustvar2 [...]]), _robust is called for each of the $2^{p}-1$ cluster combinations; details can be found in Multiway clustering of Methods and formulas in [R] regress. The model $F$ test uses the robust or cluster-robust variance estimates. There is, however, no simple computational means of obtaining a robust or cluster-robust test of the absorbed indicators. Thus, this test is not displayed when the vce (robust), vce (cluster clustvarlist), or vce(hc2 [clustvar]) option is specified.
areg with vce(hc2 [clustvar], [dfadjust]) specifies an alternative bias correction for the robust variance calculation. See Robust calculation for regress of Methods and formulas in [R] regress for a description of this VCE and the adjusted degrees of freedom.

The number of groups specified in absorb() are included in the degrees of freedom used in the finite-sample adjustment of the cluster-robust VCE estimator. This statement is valid only if the number of groups is small relative to the sample size. (Technically, the number of groups must remain fixed as the sample size grows.) For an estimator that allows the number of groups to grow with the sample size, see the xtreg, fe command in [XT] xtreg.

## Acknowledgment

We thank Sergio Correia at the Federal Reserve Board, Paulo Guimarães at the Bank of Portugal, and Fernando Rios-Avila at the Levy Economics Instute at Bard College for their work on controlling for high-dimensional categorical variables.

[^3]
## predict

## Description for predict

predict creates a new variable containing predictions such as fitted values, standard errors, residuals, and the equation-level score.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

where $y_{j}=\mathbf{x}_{j} \mathbf{b}+d_{\text {absorbvars }}+e_{j}$ and statistic is

## statistic Description

Main
$\mathrm{xb} \quad \mathbf{x}_{j} \mathbf{b}$, fitted values; the default
stdp standard error of the prediction
$\underline{\mathrm{dr}}$ esiduals $\quad d_{\text {absorbvars }}+e_{j}=y_{j}-\mathbf{x}_{j} \mathbf{b}$
*xbd $\quad \mathbf{x}_{j} \mathbf{b}+d_{\text {absorbvars }}$
*d
*residuals
$d_{\text {absorbvars }}$
*score score; equivalent to residuals
Unstarred statistics are available both in and out of sample; type predict . . . if e (sample) ... if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when if e(sample) is not specified.

## Options for predict

$\qquad$ Main
xb , the default, calculates the prediction of $\mathbf{x}_{j} \mathbf{b}$, the fitted values, by using the average effect of the absorbed variables. Also see xbd below.
stdp calculates the standard error of $\mathbf{x}_{j} \mathbf{b}$.
dresiduals calculates $y_{j}-\mathbf{x}_{j} \mathbf{b}$, which are the residuals plus the effects of the absorbed variables. xbd calculates $\mathbf{x}_{j} \mathbf{b}+d_{\text {absorbvars }}$, which are the fitted values including the effects of the absorbed variables.
d calculates $d_{\text {absorbvars }}$, the effects of the absorbed variables.
residuals calculates the residuals, that is, $y_{j}-\left(\mathbf{x}_{j} \mathbf{b}+d_{\text {absorbvars }}\right)$.
score is a synonym for residuals.

## margins

## Description for margins

margins estimates margins of response for fitted values.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [options]
```

statistic Description

| xb | $\mathbf{x}_{j} \mathbf{b}$, fitted values; the default |
| :--- | :--- |
| stdp | not allowed with margins |
| $\underline{\text { dresiduals }}$ | not allowed with margins |
| xbd | not allowed with margins |
| d | not allowed with margins |
| residuals | not allowed with margins |
| score | not allowed with margins |

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

## Remarks and examples

> Example 1
Continuing with example 1 of $[\mathrm{R}]$ areg, we refit the model with robust standard errors and then obtain linear predictions and standard errors for those linear predictions.

```
. use https://www.stata-press.com/data/r18/auto2
(1978 automobile data)
. areg mpg weight gear_ratio, absorb(rep78) vce(robust)
    (output omitted)
. predict xb_ar
(option xb assumed; fitted values)
. predict stdp_ar, stdp
```

We can obtain the same linear predictions by fitting the model with xtreg, fe, but we would first need to specify the panel structure by using xtset.

```
. xtset rep78
```

Panel variable: rep78 (unbalanced)
. xtreg mpg weight gear_ratio, fe vce(robust)
(output omitted)
. predict xb_xt
(option xb assumed; fitted values)
. predict stdp_xt, stdp
. summarize xb_ar xb_xt stdp*

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| xb_ar | 74 | 21.36805 | 4.286788 | 11.58643 | 28.07367 |
| xb_xt | 74 | 21.36805 | 4.286788 | 11.58643 | 28.07367 |
| stdp_ar | 74 | .7105649 | .1933936 | .4270821 | 1.245179 |
| stdp_xt | 74 | .8155919 | .4826332 | .0826999 | 1.709786 |

The predicted xb values above are the same for areg and xtreg, fe, but the standard errors for those linear predictions are different. The assumptions for these two estimators lead to different formulations for their standard errors. The robust variance estimates with areg are equivalent to the robust variance estimates using regress, including the panel dummies. The consistent robust variance estimates with xtreg are equivalent to those obtained by specifying vce (cluster panelvar) with that estimation command. For a theoretical discussion, see Wooldridge (2020), Stock and Watson (2008), and Arellano (2003); also see the technical note after example 3 of [XT] xtreg.

## Example 2

We would like to use linktest to check whether the dependent variable for our model is correctly specified:

```
. use https://www.stata-press.com/data/r18/auto2, clear
(1978 automobile data)
. areg mpg weight gear_ratio, absorb(rep78)
    (output omitted)
. linktest, absorb(rep78)
Linear regression, absorbing indicators Number of obs = 69
Absorbed variable: rep78 No. of categories = 5
F(2, 62) = 46.50
Prob > F = 0.0000
R-squared = 0.6939
Adj R-squared = 0.6643
Root MSE = 3.3990
```

| mpg | Coefficient | Std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | ---: | ---: |
| _hat | -.9305602 | .9537856 | -0.98 | 0.333 | -2.83715 | .9760302 |
| _hatsq | .0462785 | .0227219 | 2.04 | 0.046 | .0008582 | .0916989 |
| _cons | 19.24899 | 9.725618 | 1.98 | 0.052 | -.1922457 | 38.69022 |
| F test of absorbed indicators: $F(4,62)$ | $=1.278$ |  | Prob $>F=0.288$ |  |  |  |

The squared residuals are significant in the regression for mpg on the linear and squared residuals; therefore, the test indicates that our dependent variable does not seem to be well specified. Let's transform the dependent variable into energy consumption, gallons per mile, fit the alternative model, and check the link test again.

```
. generate gpm = 1/mpg
. areg gpm weight gear_ratio, absorb(rep78)
    (output omitted)
. linktest, absorb(rep78)
Linear regression, absorbing indicators Number of obs = 69
Absorbed variable: rep78
\begin{tabular}{llr} 
Number of obs & \(=\) & 69 \\
No. of categories & \(=\) & 5 \\
F \((2,62)\) & 72.60 \\
Prob \(>\mathrm{F}\) & \(=0.0000\) \\
R-squared & \(=0.7436\) \\
Adj R-squared & \(=0.7187\) \\
Root MSE & \(=0.0068\)
\end{tabular}
\begin{tabular}{r|rcccrr}
\hline gpm & Coefficient & Std. err. & t & P>|t| & [95\% conf. interval] \\
\hline _hat & .2842582 & .7109124 & 0.40 & 0.691 & -1.136835 & 1.705352 \\
_hatsq & 6.956965 & 6.862439 & 1.01 & 0.315 & -6.760855 & 20.67478 \\
_cons & .0175457 & .0178251 & 0.98 & 0.329 & -.0180862 & .0531777 \\
\hline F test of absorbed indicators: \(F(4,62)\) & \(=0.065\) & & Prob \(>\mathrm{F}=0.992\)
\end{tabular}
```

The link test supports the use of the transformed dependent variable.

betareg - Beta regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| Acknowledgments | References | Also see |  |

## Description

betareg estimates the parameters of a beta regression model. This model accommodates dependent variables that are greater than 0 and less than 1 , such as rates, proportions, and fractional data.

## Quick start

Beta regression of y on x 1 and x 2
betareg $y$ x1 x2
Add categorical variable a using factor-variable syntax
betareg y x1 x2 i.a
Add covariates for scale
betareg y x1 x2 i.a, scale(x1 z1)
Same as above, but use probit link for conditional mean and square-root link for conditional scale betareg y x1 x2 i.a, scale(x1 z1) link(probit) slink(root)

Beta regression of y on x 1 and x 2 with robust standard errors
betareg y x1 x 2 , vce(robust)

## Menu

indepvars and varlist specified in scale() may contain factor variables; see [U] 11.4.3 Factor variables.
bayes, bootstrap, by, collect, fmm, fp, jackknife, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: betareg and [FMM] fmm: betareg.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

$\xlongequal{\text { Model }}$
noconstant; see [R] Estimation options.
scale(varlist [, noconstant]) specifies the independent variables used to model the scale.
noconstant suppresses the constant term in the scale model. A constant term is included by default.
link(linkname) specifies the link function used for the conditional mean. linkname may be logit, probit, cloglog, or loglog. The default is link(logit).
slink(slinkname) specifies the link function used for the conditional scale. slinkname may be log, root, or identity. The default is slink(log).
constraints (constraints); see [R] Estimation options.

SE/Robust
vce (vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

```
            Reporting
level(\#), nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% fint), and nolstretch; see [R] Estimation options.
```

Maximization
maximize_options: difficult, technique (algorithm_spec), $\underline{\text { iterate }}(\#),[$ no $] \log , \underline{\text { trace }}$, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance(\#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

The following option is available with betareg but is not shown in the dialog box: coeflegend; see [R] Estimation options.

## Remarks and examples

Dependent variables such as rates, proportions, and fractional data are frequently greater than 0 and less than 1 . There are a variety of methods to model such variables, including beta regression and fractional logistic regression.

Beta regression is widely used because of its flexibility for modeling variables between 0 and 1 and because its predictions are confined to the same range. However, beta regression models are not appropriate for dependent variables with some observations exactly equal to 0 or 1 . See [R] fracreg for models when the dependent variable can equal 0 or 1 that also make predictions over the same range. The predictions from linear regression models are not constrained to the 0 to 1 interval; thus, they are not widely used for these variables.

These models have applications in a variety of disciplines, such as economics, the social sciences, and health science. For example, Castellani, Pattitoni, and Scorcu (2012) use beta regression to estimate Gini index values for the prices of art by famous and nonfamous artists. In political science, Paolino (2001) explores the advantages of beta regression and reviews its applicability for a variety of research topics such as the proportion of minority applicants deemed eligible for the Rural Housing Loans program and the proportion of a state's gay and lesbian population that is covered by antidiscrimination laws. In psychology, Smithson, Deady, and Gracik (2007) analyzed the relationship between how jurors judged the probability of a defendant's guilt and the verdict in a trial. Finally, beta regression has been used to model quality-adjusted life years in health-economics outcome studies (Hubben et al. [2008]; Basu and Manca [2012]).

Ferrari and Cribari-Neto (2004) and Smithson and Verkuilen (2006) derived the beta regression estimators implemented in betareg. Basu and Manca (2012) also discuss quasimaximum likelihood inference for these estimators. These estimators augment the inherent flexibility of the beta distribution with functional form choices, known as links.

Beta regression is a model of the mean of the dependent variable $y$ conditional on covariates $\mathbf{x}$, which we denote by $\mu_{\mathbf{x}}$. Because $y$ is in $(0,1)$, we must ensure that $\mu_{\mathbf{x}}$ is also in $(0,1)$. We do this by using the link function for the conditional mean, denoted $g(\cdot)$. This is necessary because linear combinations of the covariates are not otherwise restricted to $(0,1)$.

Algebraically,

$$
g\left(\mu_{\mathbf{x}}\right)=\mathbf{x} \boldsymbol{\beta}
$$

or, equivalently,

$$
\mu_{\mathbf{x}}=g^{-1}(\mathbf{x} \boldsymbol{\beta})
$$

where $g^{-1}(\cdot)$ is the inverse function of $g(\cdot)$. For example, the default logit link implies that

$$
\ln \left\{\mu_{\mathbf{x}} /\left(1-\mu_{\mathbf{x}}\right)\right\}=\mathbf{x} \boldsymbol{\beta}
$$

and that

$$
\mu_{\mathbf{x}}=\exp (\mathbf{x} \boldsymbol{\beta}) /\{1+\exp (\mathbf{x} \boldsymbol{\beta})\}
$$

Using a link function to keep the conditional-mean model inside an interval is common in the statistical literature; see $[R]$ glm for additional applications of link functions.

The conditional variance of the beta distribution is

$$
\operatorname{Var}(y \mid \mathbf{x})=\left\{\mu_{\mathbf{x}}\left(1-\mu_{\mathbf{x}}\right)\right\} /(1+\psi)
$$

The parameter $\psi$ is known as the scale factor because it rescales the conditional variance. We use the scale link to ensure that $\psi>0$.

## $>$ Example 1: Beta regression model of a rate

Suppose we wish to know whether offering a summer instruction program increases a school's pass rate for a mandatory state exam administered to students. The school-wide pass rate must be between 0 and 1. It is unlikely that any school will have either no students pass or all students pass, so we consider estimating the effect of the summer instruction program using beta regression.

The dataset sprogram contains fictional data on the pass rate of 1,000 schools (prate). We begin by reading in the data and verifying that prate contains no 0 s or 1 s .

```
. use https://www.stata-press.com/data/r18/sprogram
(Fictional summer program data)
```

- summarize prate

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| prate | 1,000 | .8150803 | .1233684 | .2986041 | .9973584 |

prate ranges from 0.299 to 0.997 , so we proceed with our choice of a beta regression model.
We model prate as a function of a binary indicator for whether the school offered voluntary, half-day instruction to students during the past two summers (summer). The summer program should raise the scores of disadvantaged children who otherwise would not have access to programs that maintain their skills through the summer, thereby increasing the total proportion of students who pass the exam the next year.

We include the fraction of students receiving free or reduced-price meals (freemeals) and the sum of parents' monetary donations to the school two years earlier (pdonations) as additional covariates that measure affluence of the students' parents. We estimate the parameters of this model using the default logit link for the conditional mean and log link for the conditional scale.

Log likelihood = 893.02792

| prate | Coefficient | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | :--- | ---: | ---: | ---: | ---: |
| prate |  |  |  |  |  |  |
| summer |  |  |  |  |  |  |
| Yes | .5560171 | .0480307 | 11.58 | 0.000 | .4618787 | .6501555 |
| freemeals | -.4564181 | .0834885 | -5.47 | 0.000 | -.6200525 | -.2927836 |
| pdonations | .0449706 | .0097781 | 4.60 | 0.000 | .025806 | .0641353 |
| _cons | 1.175013 | .0642797 | 18.28 | 0.000 | 1.049027 | 1.300999 |
| scale |  |  |  |  |  |  |
|  |  |  |  |  |  |  |

The output table reports the estimated coefficients of the covariates and an estimated scale parameter. The coefficient of the factor variable for summer==1, shown as yes under summer, is significant and positive. Thus we conclude that the summer program was effective at increasing a school's pass rate.

However, we cannot determine the magnitude of the effect from these results. In general, when you use betareg, the best way to obtain interpretable effect sizes for the covariates is by using margins. See example 1 in [R] betareg postestimation for more information.

## - Technical note

The results displayed in example 1 can be written concisely in algebraic form. Because we used the default logit link, the estimated conditional mean is

$$
\widehat{\mu}_{\mathbf{x}}=\exp (\mathbf{x} \widehat{\boldsymbol{\beta}}) /\{1+\exp (\mathbf{x} \widehat{\boldsymbol{\beta}})\}
$$

where the estimated $\mathbf{x} \boldsymbol{\beta}$ is

$$
\mathbf{x} \widehat{\boldsymbol{\beta}}=-0.456 \times \text { freemeals }+0.045 \times \text { pdonations }+0.556 \times(\text { summer }==1)+1.18
$$

The estimated $\psi$ with the default $\log$ link for the scale is $\widehat{\psi}=\exp (2.38)=10.80$, which is simply substituted into the formula given above to express the conditional variance.

See Methods and formulas for the functional forms of the other links implemented in betareg for the conditional mean and scale.

## > Example 2: Modeling conditional variance

Some processes require that we model the scale parameter as a function of covariates. For example, we might believe that the proportion of students with free or reduced meals influences the variance of the estimated mean.

We augment example 1 by modeling the scale parameter as a function of freemeals.

Log likelihood $=895.41544$

| prate | Coefficient | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | :--- | ---: | ---: | ---: | ---: |
| prate |  |  |  |  |  |  |
| summer |  |  |  |  |  |  |
| Yes | .5571133 | .0480378 | 11.60 | 0.000 | .4629609 | .6512658 |
| freemeals | -.5291892 | .0896511 | -5.90 | 0.000 | -.7049021 | -.3534762 |
| pdonations | .0454228 | .0097809 | 4.64 | 0.000 | .0262527 | .0645929 |
| _cons | 1.209179 | .0649585 | 18.61 | 0.000 | 1.081863 | 1.336495 |
| scale |  |  |  |  |  |  |
| freemeals | -.3598137 | .1644214 | -2.19 | 0.029 | -.6820737 | -.0375536 |
| _cons | 2.547047 | .0882327 | 28.87 | 0.000 | 2.374114 | 2.71998 |

Again, we conclude that having a summer program increases the pass rate. The effect of an increase in the proportion of students receiving free meals on the conditional variance is ambiguous because it is in both equations. We can use margins to estimate the effect of the program on the conditional mean or the conditional variance.

The estimators in betareg are consistent and efficient when the model is correctly specified. Smithson and Verkuilen (2006) discuss model selection for beta regression and note that selecting the model that minimizes the Bayesian information criterion (BIC) will select the correct model in large samples. Selecting the model that minimizes the BIC is a general approach to model selection; see Cameron and Trivedi (2005) for more details.

## > Example 3: Model selection

We fit the models quietly and use estimates store to store the results under the names model1, model2, model3, and model4.

```
. quietly betareg prate i.summer freemeals pdonations, scale(freemeals)
. estimates store model1
. quietly betareg prate i.summer freemeals pdonations, scale(freemeals)
> link(cloglog)
. estimates store model2
. quietly betareg prate i.summer freemeals pdonations, scale(freemeals)
> slink(root)
. estimates store model3
. quietly betareg prate i.summer freemeals pdonations, scale(freemeals)
> link(cloglog) slink(root)
. estimates store model4
```

Next, we use estimates table to display the coefficients, standard errors, and the BIC for each model.
. estimates table model1 model2 model3 model4, stats(bic) se

| Variable | model1 | model2 | model3 | model4 |
| :---: | :---: | :---: | :---: | :---: |
| prate |  |  |  |  |
| summer |  |  |  |  |
| Yes | .55711332 | .27762093 | .55719742 | .27765283 |
|  | .04803785 | .02460121 | .04803698 | .02459953 |
| freemeals | -.52918917 | -.25685191 | -.5300549 | -.25729221 |
| pdonations | .08965112 | .04308385 | .08978883 | .04314336 |
|  | .04542281 | .02162612 | .04542462 | .02163225 |
| _cons | 1.2091789 | .37961457 | 1.2094991 | .00444817 |
|  | .06495845 | .03212448 | .06496946 | .03212509 |
|  |  |  |  |  |
| scale |  |  |  |  |
| freemeals | -.35981368 | -.36808486 | -.59912234 | -.61295521 |
| _cons | .16442142 | .16448631 | .27259725 | .27273851 |
|  | .0882327 | .08821157 | .15204032 | .15218042 |
| Statistics |  |  |  |  |
| bic | -1749.3843 | -1749.9903 | -1749.444 | -1750.0511 |

We select model4, the model with the complementary $\log -\log$ link for the conditional mean and the square-root link for the conditional variance, because it has the lowest BIC.

## Stored results

matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r -class command is run after the estimation command.

## Methods and formulas

Beta regression models were proposed by Ferrari and Cribari-Neto (2004) and extended by Smithson and Verkuilen (2006) to allow the scale parameter to depend on covariates.

Beta regression is appropriate only for a dependent variable that is strictly greater than 0 and strictly less than 1 because the beta distribution has support only on the interval $(0,1)$. The density of a beta-distributed dependent variable $y$ conditional on covariates $\mathbf{x}$ can be written as

$$
f\left(y ; \mu_{\mathbf{x}}, \psi_{\mathbf{x}}\right)=\frac{\Gamma\left(\psi_{\mathbf{x}}\right)}{\Gamma\left(\mu_{\mathbf{x}} \psi_{\mathbf{x}}\right) \Gamma\left\{\left(1-\mu_{\mathbf{x}}\right) \psi_{\mathbf{x}}\right\}} y^{\mu_{\mathbf{x}} \psi_{\mathbf{x}}-1}(1-y)^{\left(1-\mu_{\mathbf{x}}\right) \psi_{\mathbf{x}}-1}
$$

where $\mu_{\mathbf{x}}=\mathbf{E}(y \mid \mathbf{x}), \mu_{\mathbf{x}}$ is linked to the covariates by the link function $g\left(\mu_{\mathbf{x}}\right)=\mathbf{x} \boldsymbol{\beta}, \psi_{\mathbf{x}}$ scales the conditional variance according to

$$
\operatorname{Var}(y \mid \mathbf{x})=\mu_{\mathbf{x}}\left(1-\mu_{\mathbf{x}}\right) /\left(1+\psi_{\mathbf{x}}\right)
$$

and $\psi_{\mathbf{x}}$ is linked to the covariates by link function $h\left(\psi_{\mathbf{x}}\right)=\mathbf{x} \gamma$.
This parameterization yields a log-likelihood function of

$$
\begin{aligned}
\sum_{i=1}^{N} \omega_{i}( & \ln \left\{\Gamma\left(\psi_{\mathbf{x}, i}\right)\right\}-\ln \left\{\Gamma\left(\mu_{\mathbf{x}, i} \psi_{\mathbf{x}, i}\right)\right\}-\ln \left[\Gamma\left\{\left(1-\mu_{\mathbf{x}, i}\right) \psi_{\mathbf{x}, i}\right\}\right] \\
& \left.+\left(\mu_{\mathbf{x}, i} \psi_{\mathbf{x}, i}-1\right) \ln \left(y_{i}\right)+\left\{\left(1-\mu_{\mathbf{x}, i}\right) \psi_{\mathbf{x}, i}-1\right\} \ln \left(1-y_{i}\right)\right)
\end{aligned}
$$

The definitions of the link functions are

| Name | Function |
| :--- | :--- |
| logit | $g\left(\mu_{\mathbf{x}}\right)=\ln \left\{\mu_{\mathbf{x}} /\left(1-\mu_{\mathbf{x}}\right)\right\}$ |
| probit | $g\left(\mu_{\mathbf{x}}\right)=\Phi^{-1}\left(\mu_{\mathbf{x}}\right)$ |
| cloglog | $g\left(\mu_{\mathbf{x}}\right)=\ln \left\{-\ln \left(1-\mu_{\mathbf{x}}\right)\right\}$ |
| loglog | $g\left(\mu_{\mathbf{x}}\right)=-\ln \left\{-\ln \left(\mu_{\mathbf{x}}\right)\right\}$ |

The definitions of the scale-link functions are

| Name | Function |
| :--- | :--- |
| $\log$ | $h\left(\psi_{\mathbf{x}}\right)=\ln \left(\psi_{\mathbf{x}}\right)$ |
| root | $h\left(\psi_{\mathbf{x}}\right)=\sqrt{\psi_{\mathbf{x}}}$ |
| identity | $h\left(\psi_{\mathbf{x}}\right)=\psi_{\mathbf{x}}$ |

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce (robust) and vce (cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.

## Title

betareg postestimation - Postestimation tools for betareg
Postestimation commands predict margins Remarks and examples

## Postestimation commands

The following postestimation commands are available after betareg:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estat (svy) | postestimation statistics for survey data |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| * forecast | dynamic forecasts and simulations |
| * hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| * 1 rtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | conditional means and variances, linear predictions, etc. |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| suest | seemingly unrelated estimation |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

[^4]
## predict

## Description for predict

predict creates a new variable containing predictions such as linear predictions, conditional means, conditional variances, and equation-level scores.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

predict [type] newvar [if] [in] [, statistic]
predict [type] stub* [if] [in], scores

## statistic Description

Main

| cmean | conditional mean of the dependent variable; the default <br> conditional variance of the dependent variable |
| :--- | :--- |
| $\frac{\mathrm{xb}}{\mathrm{xb}} \mathrm{lance}$ | linear prediction in the conditional-mean equation |
| xbscale | linear prediction in the conditional-scale equation <br> stdp |

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

## Options for predict

$\qquad$ Main
cmean, the default, calculates the conditional mean of the dependent variable. cvariance calculates the conditional variance of the dependent variable. xb calculates the linear prediction for the conditional-mean equation.
xbscale calculates the linear prediction for the conditional-scale equation.
stdp calculates the standard error of the linear prediction for the conditional-mean equation.
scores calculates equation-level score variables. The first new variable will contain the derivative of the log likelihood with respect to the conditional-mean equation, and the second new variable will contain the derivative of the log likelihood with respect to the conditional-scale equation.

## margins

## Description for margins

margins estimates margins of response for conditional means, conditional variances, and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...)...] [options]
```

statistic Description

| cmean | conditional mean of the dependent variable; the default <br> conditional variance of the dependent variable |
| :--- | :--- |
| $\underline{\mathrm{cvar}} \mathrm{iance}$ | linear prediction in the conditional-mean equation |
| xbscale | linear prediction in the conditional-scale equation |
| stdp | not allowed with margins |
| scores | not allowed with margins |

Statistics not allowed with margins are functions of stochastic quantities other than e(b). For the full syntax, see [R] margins.

## Remarks and examples

## > Example 1

In example 3 in [R] betareg, we selected a model for school-level data on the fraction of students passing a state-required exam. In that example, we were interested in whether a voluntary summer program increased schools' pass rates. We continue that example to estimate an average treatment effect (ATE) of the program.

After reading in the data and fitting the model, we use margins to estimate the ATE.

```
. use https://www.stata-press.com/data/r18/sprogram
(Fictional summer program data)
. betareg prate freemeals pdonations i.summer, scale(freemeals) link(cloglog)
> slink(root) vce(robust)
    (output omitted)
```

We specify vce(robust) with the estimation command and vce(unconditional) with the margins command to obtain standard errors for a population ATE instead of a sample ATE.

```
. margins r.summer, contrast(nowald) vce(unconditional)
Contrasts of predictive margins Number of obs = 1,000
```

Expression: Conditional mean of prate, predict()

|  | Unconditional <br> std. err. |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| [95\% conf. interval] |  |  |  |  |
| (Yes vs No) | .0890851 | .008626 | .0721784 | .1059918 |

The average pass rate would be about $9 \%$ higher when all schools offered the program than when no school offered the program.

## Title

binreg - Generalized linear models: Extensions to the binomial family

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

binreg fits generalized linear models for the binomial family. It estimates odds ratios, risk ratios, health ratios, and risk differences. The available links are

| Option | Implied link | Parameter |
| ---: | ---: | ---: |
| or | logit | odds ratios $=\exp (\beta)$ |
| rr | log | risk ratios $=\exp (\beta)$ |
| hr | log complement | health ratios $=\exp (\beta)$ |
| rd | identity | risk differences $=\beta$ |

Estimates of odds, risk, and health ratios are obtained by exponentiating the appropriate coefficients. The or option produces the same results as Stata's logistic command, and or coefficients yields the same results as the logit command. When no link is specified, or is assumed.

## Quick start

Report odds ratios from a model of y on x 1 and x 2 using a logit link
binreg y x1 x2, or
Use the $\log$ link and report risk ratios
binreg y x1 x2, rr
Use the identity link and report risk differences
binreg y x1 x2, rd
Same as above, but with data stored as the number of successes, ys, out of $n$ trials
binreg ys x 1 x 2 , rd $\mathrm{n}(\mathrm{n})$

## Menu

Statistics $>$ Generalized linear models $>$ GLM for the binomial family

use varname as the initial estimate for the mean of depvar synonym for mu(varname)
vcetype may be eim, robust, cluster clustvar, oim, opg, bootstrap, jackknife, hac kernel, jackknife1, or unbiased
variable name corresponding to time
multiply variance matrix by scalar \#
quasilikelihood multiplier
set the scale parameter; default is scale(1)
set confidence level; default is level (95)
report nonexponentiated coefficients
do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
use iterated, reweighted least-squares optimization; the default use maximum likelihood optimization
control the maximization process; seldom used
Fisher scoring steps
search for good starting values
keep collinear variables
display legend instead of statistics
indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bayes, bootstrap, by, collect, fp, jackknife, mi estimate, rolling, and statsby are allowed; see
[U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: binreg.
vce(bootstrap), vce(jackknife), and vce(jackknife1) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

Model
noconstant; see [R] Estimation options.
or requests the logit link and results in odds ratios if coefficients is not specified.
rr requests the log link and results in risk ratios if coefficients is not specified.
hr requests the log-complement link and results in health ratios if coefficients is not specified. rd requests the identity link and results in risk differences.
n (\#|varname) specifies either a constant integer to use as the denominator for the binomial family or a variable that holds the denominator for each observation.
exposure(varname), offset (varname), constraints(constraints); see [R] Estimation options. constraints (constraints) is not allowed with irls.
mu (varname) specifies varname containing an initial estimate for the mean of depvar. This option can be useful if you encounter convergence difficulties. init(varname) is a synonym.

SE/Robust
vce (vcetype) specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), that are derived from asymptotic theory (oim, opg), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
vce (eim), the default, uses the expected information matrix (EIM) for the variance estimator.
binreg also allows the following:
vce (hac kernel [\#]) specifies that a heteroskedasticity- and autocorrelation-consistent (HAC) variance estimate be used. HAC refers to the general form for combining weighted matrices to form the variance estimate. There are three kernels built into binreg. kernel is a user-written program or one of

```
nwest | gallant | anderson
```

If \# is not specified, $N-2$ is assumed.
vce (jackknife1) specifies that the one-step jackknife estimate of variance be used.
vce (unbiased) specifies that the unbiased sandwich estimate of variance be used.
t(varname) specifies the variable name corresponding to time; see [TS] tsset. binreg does not always need to know $t$ (), though it does if vce (hac ...) is specified. Then you can either specify the time variable with $t$ (), or you can tsset your data before calling binreg. When the time variable is required, binreg assumes that the observations are spaced equally over time.
vfactor(\#) specifies a scalar by which to multiply the resulting variance matrix. This option allows users to match output with other packages, which may apply degrees of freedom or other small-sample corrections to estimates of variance.
disp(\#) multiplies the variance of depvar by \# and divides the deviance by \#. The resulting distributions are members of the quasilikelihood family. This option is not allowed with option ml.
scale (x2|dev|\#) overrides the default scale parameter. This option is allowed only with Hessian (information matrix) variance estimates.
By default, scale(1) is assumed for the discrete distributions (binomial, Poisson, and negative binomial), and scale (x2) is assumed for the continuous distributions (Gaussian, gamma, and inverse Gaussian).
scale ( x 2 ) specifies that the scale parameter be set to the Pearson $\chi^{2}$ (or generalized $\chi^{2}$ ) statistic divided by the residual degrees of freedom, which is recommended by McCullagh and Nelder (1989) as a good general choice for continuous distributions.
scale(dev) sets the scale parameter to the deviance divided by the residual degrees of freedom. This option provides an alternative to scale (x2) for continuous distributions and overdispersed or underdispersed discrete distributions. This option is not allowed with option ml .
scale(\#) sets the scale parameter to \#.

## Reporting <br> level (\#), noconstant; see [R] Estimation options.

coefficients displays the nonexponentiated coefficients and corresponding standard errors and confidence intervals. This option has no effect when the rd option is specified, because it always presents the nonexponentiated coefficients.
nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\% fint), pformat (\% fint), sformat (\% fint), and nolstretch; see [R] Estimation options.

## Maximization

irls requests iterated, reweighted least-squares (IRLS) optimization of the deviance instead of Newton-Raphson optimization of the log likelihood. This option is the default.
ml requests that optimization be carried out by using Stata's ml command; see [R] ml. maximize_options: difficult, technique (algorithm_spec), iterate (\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance(\#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.
Setting the optimization method to ml , with technique () set to something other than BHHH, changes the vcetype to vce (oim). Specifying technique (bhhh) changes vcetype to vce (opg).
Unless option ml is specified, only maximize_options iterate(), nolog, trace, and ltolerance() are allowed. With IRLS optimization, the convergence criterion is satisfied when the
absolute change in deviance from one iteration to the next is less than or equal to ltolerance(), where ltolerance $(1 e-6)$ is the default.
fisher (\#) specifies the number of Newton-Raphson steps that should use the Fisher scoring Hessian or EIM before switching to the observed information matrix (OIM). This option is available only if ml is specified and is useful only for Newton-Raphson optimization.
search specifies that the command search for good starting values. This option is available only if ml is specified and is useful only for Newton-Raphson optimization.

The following options are available with binreg but are not shown in the dialog box:
collinear, coeflegend; see [R] Estimation options. collinear is not allowed with irls.

## Remarks and examples

Wacholder (1986) suggests methods for estimating risk ratios and risk differences from prospective binomial data. These estimates are obtained by selecting the proper link functions in the generalized linear-model framework. (See Methods and formulas for details; also see [R] glm.)

## > Example 1

Wacholder (1986) presents an example, using data from Wright et al. (1983), of an investigation of the relationship between alcohol consumption and the risk of a low-birthweight baby. Covariates examined included whether the mother smoked (yes or no), mother's social class (three levels), and drinking frequency (light, moderate, or heavy). The data for the 18 possible categories determined by the covariates are illustrated below.

Let's first describe the data and list a few observations.
. use https://www.stata-press.com/data/r18/binreg (Alcohol and low-birthweight baby) . list

|  | category | n_lbw_~s | n_women | alcohol | smokes | social |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1. | 1 | 11 | 84 | Heavy | Nonsmoker | 1 |
| 2. | 2 | 5 | 79 | Moderate | Nonsmoker | 1 |
| 3. | 3 | 11 | 169 | Light | Nonsmoker | 1 |
| 4. | 4 | 6 | 28 | Heavy | Smoker | 1 |
| 5. | 5 | 3 | 13 | Moderate | Smoker | 1 |
| 6. | 6 | 1 | 26 | Light | Smoker | 1 |
| 7. | 7 | 4 | 22 | Heavy | Nonsmoker | 2 |
| 8. | 8 | 3 | 25 | Moderate | Nonsmoker | 2 |
| 9. | 9 | 12 | 162 | Light | Nonsmoker | 2 |
| 10. | 10 | 4 | 17 | Heavy | Smoker | 2 |
| 11. | 11 | 2 | 7 | Moderate | Smoker | 2 |
| 12. | 12 | 6 | 38 | Light | Smoker | 2 |
| 13. | 13 | 0 | 14 | Heavy | Nonsmoker | 3 |
| 14. | 14 | 1 | 18 | Moderate | Nonsmoker | 3 |
| 15. | 15 | 12 | 91 | Light | Nonsmoker | 3 |
| 16. | 16 | 7 | 19 | Heavy | Smoker | 3 |
| 17. | 17 | 2 | 18 | Moderate | Smoker | 3 |
| 18. | 18 | 8 | 70 | Light | Smoker | 3 |

Each observation corresponds to one of the 18 covariate structures. The number of low-birthweight babies from n_women in each category is given by the $n \_l b w \_b a b i e s ~ v a r i a b l e . ~$

We begin by estimating risk ratios:

Note: _cons estimates baseline risk.
By default, Stata reports the risk ratios (the exponentiated regression coefficients) estimated by the model. We can see that the risk ratio comparing heavy drinkers with light drinkers, after adjusting for smoking and social class, is 1.974078 . That is, mothers who drink heavily during their pregnancy have approximately twice the risk of delivering low-birthweight babies as mothers who are light drinkers.

The nonexponentiated coefficients can be obtained with the coefficients option:

```
. binreg n_lbw_babies i.soc i.alc i.smo, n(n_women) rr coefficients
Iteration 1: Deviance = 14.2879
Iteration 2: Deviance = 13.607
Iteration 3: Deviance = 13.60503
Iteration 4: Deviance = 13.60503
```

Generalized linear models $\quad$ Number of obs $=18$

BIC $=-21.07943$

| n_lbw_babies | Coefficient | $\begin{gathered} \text { EIM } \\ \text { std. err. } \end{gathered}$ | z | $P>\|z\|$ | [95\% conf | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| social |  |  |  |  |  |  |
| 2 | . 2926702 | . 2333866 | 1.25 | 0.210 | -. 1647591 | . 7500994 |
| 3 | . 2997244 | . 2439066 | 1.23 | 0.219 | -. 1783238 | . 7777726 |
| alcohol |  |  |  |  |  |  |
| Moderate | . 1749248 | . 274133 | 0.64 | 0.523 | -. 362366 | . 7122156 |
| Heavy | . 6801017 | . 2158856 | 3.15 | 0.002 | . 2569737 | 1.10323 |
| smokes |  |  |  |  |  |  |
| Smoker | . 4998317 | . 2019329 | 2.48 | 0.013 | . 1040505 | . 8956129 |
| _cons | -2.764079 | . 2031606 | -13.61 | 0.000 | -3.162266 | -2.365891 |

Risk differences are obtained with the rd option:

The risk difference between heavy drinkers and light drinkers is 0.0801291 . Because the risk differences are obtained directly from the coefficients estimated by using the identity link, the coefficients option would have no effect here.

Health ratios are obtained with the hr option. The health ratios (exponentiated coefficients for the log-complement link) are reported directly.

## Methods and formulas

Let $\pi_{i}$ be the probability of success for the $i$ th observation, $i=1, \ldots, N$, and let $X \beta$ be the linear predictor. The link function relates the covariates of each observation to its respective probability through the linear predictor.

In logistic regression, the logit link is used:

$$
\ln \left(\frac{\pi}{1-\pi}\right)=X \beta
$$

The regression coefficient $\beta_{k}$ represents the change in the logarithm of the odds associated with a one-unit change in the value of the $X_{k}$ covariate; thus, $\exp \left(\beta_{k}\right)$ is the ratio of the odds associated with a change of one unit in $X_{k}$.

For risk differences, the identity link $\pi=X \beta$ is used. The regression coefficient $\beta_{k}$ represents the risk difference associated with a change of one unit in $X_{k}$. When using the identity link, you can obtain fitted probabilities outside the interval $(0,1)$. As suggested by Wacholder, at each iteration,
fitted probabilities are checked for range conditions (and put back in range if necessary). For example, if the identity link results in a fitted probability that is smaller than $1 \mathrm{e}-4$, the probability is replaced with $1 \mathrm{e}-4$ before the link function is calculated.

A similar adjustment is made for the logarithmic link, which is used for estimating the risk ratio, $\ln (\pi)=X \beta$, where $\exp \left(\beta_{k}\right)$ is the risk ratio associated with a change of one unit in $X_{k}$, and for the log-complement link used to estimate the probability of no disease or health, where $\exp \left(\beta_{k}\right)$ represents the "health ratio" associated with a change of one unit in $X_{k}$.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce (robust) and vce (cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.

binreg postestimation - Postestimation tools for binreg

Postestimation commands predict margins References Also see

## Postestimation commands

The following postestimation commands are available after binreg:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| *estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| $\dagger$ forecast | dynamic forecasts and simulations |
| hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| linktest | link test for model specification |
| *lrtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |

[^5]
## predict

## Description for predict

predict creates a new variable containing predictions such as expected values, linear predictions, standard errors, residuals, Cook's distance, diagonals, weighted averages, differences, and first derivatives.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

predict [type] newvar [if] [in] [, statistic options]
statistic Description
Main
mu expected value of $y$; the default
$\mathrm{xb} \quad$ linear prediction $\eta=\mathbf{x} \widehat{\boldsymbol{\beta}}$
eta synonym for xb
stdp standard error of the linear prediction
anscombe Anscombe (1953) residuals
cooksd
deviance
hat diagonals of the "hat" matrix
likelihood
pearson
response
score
working
Cook's distance
deviance residuals

Pearson residuals
working residuals
weighted average of the standardized deviance and standard Pearson residuals
differences between the observed and fitted outcomes
first derivative of the log likelihood with respect to $\mathbf{x}_{j} \boldsymbol{\beta}$
options
Options
nooffset
adjusted standardized studentized modified

Description
modify calculations to ignore the offset variable
adjust deviance residual to speed up convergence
multiply residual by the factor $(1-h)^{1 / 2}$
multiply residual by one over the square root of the estimated scale parameter modify denominator of residual to be a reasonable estimate of the variance of depvar

These statistics are available both in and out of sample; type predict . . . if e(sample) ... if wanted only for the estimation sample.

## Options for predict

$\qquad$
mu , the default, specifies that predict calculate the expected value of $y$, equal to $g^{-1}(\mathbf{x} \widehat{\boldsymbol{\beta}})\left[n g^{-1}(\mathbf{x} \widehat{\boldsymbol{\beta}})\right.$ for the binomial family].
xb calculates the linear prediction $\eta=\mathbf{x} \widehat{\boldsymbol{\beta}}$.
eta is a synonym for xb .
stdp calculates the standard error of the linear prediction.
anscombe calculates the Anscombe (1953) residuals to produce residuals that closely follow a normal distribution.
cooksd calculates Cook's distance, which measures the aggregate change in the estimated coefficients when each observation is left out of the estimation.
deviance calculates the deviance residuals, which are recommended by McCullagh and Nelder (1989) and others as having the best properties for examining goodness of fit of a GLM. They are approximately normally distributed if the model is correct and may be plotted against the fitted values or against a covariate to inspect the model's fit. Also see the pearson option below.
hat calculates the diagonals of the "hat" matrix, analogous to linear regression.
likelihood calculates a weighted average of the standardized deviance and standardized Pearson (described below) residuals.
pearson calculates the Pearson residuals, which often have markedly skewed distributions for nonnormal family distributions. Also see the deviance option above.
response calculates the differences between the observed and fitted outcomes.
score calculates the equation-level score, $\partial \ln L / \partial\left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$.
working calculates the working residuals, which are response residuals weighted according to the derivative of the link function.

## Options

nooffset is relevant only if you specified offset (varname) for binreg. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_{j} \mathbf{b}$ rather than as $\mathbf{x}_{j} \mathbf{b}+$ offset $_{j}$.
adjusted adjusts the deviance residual to make the convergence to the limiting normal distribution faster. The adjustment deals with adding to the deviance residual a higher-order term depending on the variance function family. This option is allowed only when deviance is specified.
standardized requests that the residual be multiplied by the factor $(1-h)^{-1 / 2}$, where $h$ is the diagonal of the hat matrix. This step is done to take into account the correlation between depvar and its predicted value.
studentized requests that the residual be multiplied by one over the square root of the estimated scale parameter.
modified requests that the denominator of the residual be modified to be a reasonable estimate of the variance of depvar. The base residual is multiplied by the factor $(k / w)^{-1 / 2}$, where $k$ is either one or the user-specified dispersion parameter and $w$ is the specified weight (or one if left unspecified).

## margins

## Description for margins

margins estimates margins of response for expected values and linear predictions.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...)...] [options]
```

statistic Description
mu expected value of $y$; the default
$\mathrm{xb} \quad$ linear prediction $\eta=\mathbf{x} \widehat{\boldsymbol{\beta}}$
eta synonym for xb
stdp not allowed with margins
anscombe not allowed with margins
cooksd not allowed with margins
deviance not allowed with margins
hat not allowed with margins
likelihood not allowed with margins
pearson not allowed with margins
response not allowed with margins
score not allowed with margins
working not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

## Title

biprobit - Bivariate probit regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

biprobit fits maximum-likelihood two-equation probit models—either a bivariate probit or a seemingly unrelated probit (limited to two equations).

## Quick start

Bivariate probit regression of y 1 and y 2 on x 1
biprobit y1 y2 x1
Bivariate probit regression of y 1 and y 2 on x 1 , x 2 , and x 3
biprobit y1 y2 x1 x2 x3
Constrain the coefficients for x 1 to equality in both equations
constraint define 1 _b[y1:x1] = _b[y2:x1]
biprobit y1 y2 x1 x2 x3, constraints(1)
Seemingly unrelated bivariate probit regression
biprobit ( $\mathrm{y} 1=\mathrm{x} 1 \mathrm{x} 2 \mathrm{x} 3$ ) ( $\mathrm{y} 2=\mathrm{x} 1 \mathrm{x} 2)$
With robust standard errors
biprobit ( $\mathrm{y} 1=\mathrm{x} 1 \mathrm{x} 2 \mathrm{x} 3$ ) ( y 2 = x 1 x 2 ), vce(robust)
Poirier partial observability model with difficult option
biprobit ( $\mathrm{y} 1=\mathrm{x} 1 \mathrm{x} 2$ ) ( $\mathrm{y} 2=\mathrm{x} 2 \mathrm{x} 3)$, partial difficult

## Menu

Description
suppress constant term
fit partial observability model
offset variable for first equation
offset variable for second equation
apply specified linear constraints
vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife
set confidence level; default is level (95)
perform the likelihood-ratio model test instead of the default Wald test do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

Maximization
maximize_options
collinear
coeflegend
control the maximization process; seldom used
keep collinear variables
display legend instead of statistics

## su_options

Description
Model
partial
constraints (constraints)
SE/Robust
vce (vcetype)

Reporting
level(\#)
lrmodel
nocnsreport
display_options

Maximization
maximize_options
collinear
coeflegend
fit partial observability model
apply specified linear constraints
vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife
set confidence level; default is level (95)
perform the likelihood-ratio model test instead of the default Wald test do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
control the maximization process; seldom used
keep collinear variables
display legend instead of statistics
indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
depvar ${ }_{1}$, depvar ${ }_{2}$, indepvars, and depvar may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bayes, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: biprobit.
Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
vce(), lrmodel, and weights are not allowed with the svy prefix; see [SVY] svy.
pweights, fweights, and iweights are allowed; see [U] 11.1.6 weight.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

$\qquad$ Model
noconstant; see [R] Estimation options.
partial specifies that the partial observability model be fit. This particular model commonly has poor convergence properties, so we recommend that you use the difficult option if you want to fit the Poirier partial observability model; see [R] Maximize.

This model computes the product of the two dependent variables so that you do not have to replace each with the product.
offset1(varname), offset2(varname), constraints (constraints); see [R] Estimation options.
vce (vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
$\qquad$ Reporting
level(\#), lrmodel, nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% fmt), and nolstretch; see [R] Estimation options.

Maximization
maximize_options: difficult, technique (algorithm_spec), iterate(\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance(\#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique (bhhh) resets the default vcetype to vce (opg).
The following options are available with biprobit but are not shown in the dialog box:
collinear, coeflegend; see [R] Estimation options.

## Remarks and examples

For a good introduction to the bivariate probit models, see Greene (2018, sec. 17.9) and Pindyck and Rubinfeld (1998). Poirier (1980) explains the partial observability model. Van de Ven and Van Pragg (1981) explain the probit model with sample selection; see $[R]$ heckprobit for details.

## > Example 1

We use the data from Pindyck and Rubinfeld (1998, 332). In this dataset, the variables are whether children attend private school (private), number of years the family has been at the present residence (years), log of property tax (logptax), log of income (loginc), and whether the head of the household voted for an increase in property taxes (vote).

We wish to model the bivariate outcomes of whether children attend private school and whether the head of the household voted for an increase in property tax based on the other covariates.
. use https://www.stata-press.com/data/r18/school
. biprobit private vote years logptax loginc
Fitting comparison equation 1 :

```
Iteration 0: Log likelihood = -31.967097
Iteration 1: Log likelihood = -31.452424
Iteration 2: Log likelihood = -31.448958
Iteration 3: Log likelihood = -31.448958
Fitting comparison equation 2:
Iteration 0: Log likelihood = -63.036914
Iteration 1: Log likelihood = -58.534843
Iteration 2: Log likelihood = -58.497292
Iteration 3: Log likelihood = -58.497288
Comparison: Log likelihood = -89.946246
Fitting full model:
Iteration 0: Log likelihood = -89.946246
Iteration 1: Log likelihood = -89.258897
Iteration 2: Log likelihood = -89.254028
Iteration 3: Log likelihood = -89.254028
Bivariate probit regression Number of obs = 95
Wald chi2(6) = 9.59
Prob > chi2 = 0.1431
```

The output shows several iteration logs. The first iteration $\log$ corresponds to running the univariate probit model for the first equation, and the second log corresponds to running the univariate probit for the second model. If $\rho=0$, the sum of the log likelihoods from these two models will equal the $\log$ likelihood of the bivariate probit model; this sum is printed in the iteration $\log$ as the comparison log likelihood.

The final iteration $\log$ is for fitting the full bivariate probit model. A likelihood-ratio test of the $\log$ likelihood for this model and the comparison $\log$ likelihood is presented at the end of the output. If we had specified the vce (robust) option, this test would be presented as a Wald test instead of as a likelihood-ratio test.

We could have fit the same model by using the seemingly unrelated syntax as

[^6]
## Stored results

In addition to the above, the following is stored in r() :
Matrices
$r(t a b l e) \quad$ matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r$ () are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

The $\log$ likelihood, $\ln L$, is given by

$$
\begin{aligned}
\xi_{j}^{\beta} & =x_{j} \beta+\text { offset }_{j}^{\beta} \\
\xi_{j}^{\gamma} & =z_{j} \gamma+\text { offset }_{j}^{\gamma} \\
q_{1 j} & = \begin{cases}1 & \text { if } y_{1 j} \neq 0 \\
-1 & \text { otherwise }\end{cases} \\
q_{2 j} & = \begin{cases}1 & \text { if } y_{2 j} \neq 0 \\
-1 & \text { otherwise }\end{cases} \\
\rho_{j}^{*} & =q_{1 j} q_{2 j} \rho \\
\ln L & =\sum_{j=1}^{n} w_{j} \ln \Phi_{2}\left(q_{1 j} \xi_{j}^{\beta}, q_{2 j} \xi_{j}^{\gamma}, \rho_{j}^{*}\right)
\end{aligned}
$$

where $\Phi_{2}()$ is the cumulative bivariate normal distribution function (with mean $\left[\begin{array}{ll}0 & 0\end{array}\right]^{\prime}$ ) and $w_{j}$ is an optional weight for observation $j$. This derivation assumes that

$$
\begin{aligned}
y_{1 j}^{*} & =x_{j} \beta+\epsilon_{1 j}+\operatorname{offset}_{j}^{\beta} \\
y_{2 j}^{*} & =z_{j} \gamma+\epsilon_{2 j}+\operatorname{offset}_{j}^{\gamma} \\
E\left(\epsilon_{1}\right) & =E\left(\epsilon_{2}\right)=0 \\
\operatorname{Var}\left(\epsilon_{1}\right) & =\operatorname{Var}\left(\epsilon_{2}\right)=1 \\
\operatorname{Cov}\left(\epsilon_{1}, \epsilon_{2}\right) & =\rho
\end{aligned}
$$

where $y_{1 j}^{*}$ and $y_{2 j}^{*}$ are the unobserved latent variables; instead, we observe only $y_{i j}=1$ if $y_{i j}^{*}>0$ and $y_{i j}=0$ otherwise (for $i=1,2$ ).

In the maximum likelihood estimation, $\rho$ is not directly estimated, but atanh $\rho$ is

$$
\operatorname{atanh} \rho=\frac{1}{2} \ln \left(\frac{1+\rho}{1-\rho}\right)
$$

From the form of the likelihood, if $\rho=0$, then the log likelihood for the bivariate probit models is equal to the sum of the $\log$ likelihoods of the two univariate probit models. A likelihood-ratio test may therefore be performed by comparing the likelihood of the full bivariate model with the sum of the log likelihoods for the univariate probit models.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce(robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.
biprobit also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

statistic Description

## Main

p11
$\Phi_{2}\left(\mathbf{x}_{j} \mathbf{b}, \mathbf{z}_{j} \mathbf{g}, \rho\right)$, predicted probability $\operatorname{Pr}\left(y_{1 j}=1, y_{2 j}=1\right)$; the default
p10
$\Phi_{2}\left(\mathbf{x}_{j} \mathbf{b},-\mathbf{z}_{j} \mathbf{g},-\rho\right)$, predicted probability $\operatorname{Pr}\left(y_{1 j}=1, y_{2 j}=0\right)$
$\Phi_{2}\left(-\mathbf{x}_{j} \mathbf{b}, \mathbf{z}_{j} \mathbf{g},-\rho\right)$, predicted probability $\operatorname{Pr}\left(y_{1 j}=0, y_{2 j}=1\right)$
p00
pmarg1
$\Phi_{2}\left(-\mathbf{x}_{j} \mathbf{b},-\mathbf{z}_{j} \mathbf{g}, \rho\right)$, predicted probability $\operatorname{Pr}\left(y_{1 j}=0, y_{2 j}=0\right)$
pmarg2
$\Phi\left(\mathbf{x}_{j} \mathbf{b}\right)$, marginal success probability for equation 1
pcond1
$\Phi\left(\mathbf{z}_{j} \mathbf{g}\right)$, marginal success probability for equation 2
pcond2
xb1
$\Phi_{2}\left(\mathbf{x}_{j} \mathbf{b}, \mathbf{z}_{j} \mathbf{g}, \rho\right) / \Phi\left(\mathbf{z}_{j} \mathbf{g}\right)$, conditional probability of success for equation 1
xb2
$\mathbf{x}_{j} \mathbf{b}$, linear prediction for equation 1
stdp1
$\mathbf{z}_{j} \mathbf{g}$, linear prediction for equation 2
standard error of the linear prediction for equation 1
stdp2
standard error of the linear prediction for equation 2
where $\Phi(\cdot)$ is the standard normal-distribution function and $\Phi_{2}(\cdot)$ is the bivariate standard normal-distribution function.

These statistics are available both in and out of sample; type predict ... if e(sample)... if wanted only for the estimation sample.

## Options for predict

p11, the default, calculates the bivariate predicted probability $\operatorname{Pr}\left(y_{1 j}=1, y_{2 j}=1\right)$.
p10 calculates the bivariate predicted probability $\operatorname{Pr}\left(y_{1 j}=1, y_{2 j}=0\right)$.
p01 calculates the bivariate predicted probability $\operatorname{Pr}\left(y_{1 j}=0, y_{2 j}=1\right)$.
p00 calculates the bivariate predicted probability $\operatorname{Pr}\left(y_{1 j}=0, y_{2 j}=0\right)$.
pmarg1 calculates the univariate (marginal) predicted probability of success $\operatorname{Pr}\left(y_{1 j}=1\right)$. pmarg2 calculates the univariate (marginal) predicted probability of success $\operatorname{Pr}\left(y_{2 j}=1\right)$. pcond1 calculates the conditional (on success in equation 2 ) predicted probability of success $\operatorname{Pr}\left(y_{1 j}=1, y_{2 j}=1\right) / \operatorname{Pr}\left(y_{2 j}=1\right)$.
pcond2 calculates the conditional (on success in equation 1) predicted probability of success
$\operatorname{Pr}\left(y_{1 j}=1, y_{2 j}=1\right) / \operatorname{Pr}\left(y_{1 j}=1\right)$.
xb 1 calculates the probit linear prediction $\mathbf{x}_{j} \mathbf{b}$.
xb 2 calculates the probit linear prediction $\mathbf{z}_{j} \mathbf{g}$.
stdp1 calculates the standard error of the linear prediction for equation 1.
stdp2 calculates the standard error of the linear prediction for equation 2.
nooffset is relevant only if you specified offset1 (varname) or offset2 (varname) for biprobit. It modifies the calculations made by predict so that they ignore the offset variables; the linear predictions are treated as $\mathbf{x}_{j} \mathbf{b}$ rather than as $\mathbf{x}_{j} \mathbf{b}+\operatorname{offset}_{1 \mathrm{j}}$ and $\mathbf{z}_{j} \gamma$ rather than as $\mathbf{z}_{j} \gamma+$ offset $_{2 j}$. scores calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial\left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$.
The second new variable will contain $\partial \ln L / \partial\left(\mathbf{z}_{j} \gamma\right)$.
The third new variable will contain $\partial \ln L / \partial(\operatorname{atanh} \rho)$.

## margins

## Description for margins

margins estimates margins of response for probabilities and linear predictions.

## Menu for margins

## statistic Description

p11 $\quad \Phi_{2}\left(\mathbf{x}_{j} \mathbf{b}, \mathbf{z}_{j} \mathbf{g}, \rho\right)$, predicted probability $\operatorname{Pr}\left(y_{1 j}=1, y_{2 j}=1\right)$; the default
p10 $\Phi_{2}\left(\mathbf{x}_{j} \mathbf{b},-\mathbf{z}_{j} \mathbf{g},-\rho\right)$, predicted probability $\operatorname{Pr}\left(y_{1 j}=1, y_{2 j}=0\right)$
p01 $\quad \Phi_{2}\left(-\mathbf{x}_{j} \mathbf{b}, \mathbf{z}_{j} \mathbf{g},-\rho\right)$, predicted probability $\operatorname{Pr}\left(y_{1 j}=0, y_{2 j}=1\right)$
p00 $\quad \Phi_{2}\left(-\mathbf{x}_{j} \mathbf{b},-\mathbf{z}_{j} \mathbf{g}, \rho\right)$, predicted probability $\operatorname{Pr}\left(y_{1 j}=0, y_{2 j}=0\right)$
pmarg1 $\Phi\left(\mathbf{x}_{j} \mathbf{b}\right)$, marginal success probability for equation 1
pmarg2 $\quad \Phi\left(\mathbf{z}_{j} \mathbf{g}\right)$, marginal success probability for equation 2
pcond1 $\quad \Phi_{2}\left(\mathbf{x}_{j} \mathbf{b}, \mathbf{z}_{j} \mathbf{g}, \rho\right) / \Phi\left(\mathbf{z}_{j} \mathbf{g}\right)$, conditional probability of success for equation 1
pcond2 $\quad \Phi_{2}\left(\mathbf{x}_{j} \mathbf{b}, \mathbf{z}_{j} \mathbf{g}, \rho\right) / \Phi\left(\mathbf{x}_{j} \mathbf{b}\right)$, conditional probability of success for equation 2
xb1
$\mathbf{x}_{j} \mathbf{b}$, linear prediction for equation 1
$\mathrm{xb} 2 \quad \mathbf{z}_{j} \mathbf{g}$, linear prediction for equation 2
stdp1 not allowed with margins
stdp2 not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see $[R]$ margins.

## Title

bitest - Binomial probability test

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Option | Remarks and examples | Stored results | Methods and formulas |
| Reference | Also see |  |  |

## Description

bitest performs exact hypothesis tests for binomial random variables. The null hypothesis is that the probability of a success on a trial is $\#_{p}$. The total number of trials is the number of nonmissing values of varname (in bitest) or $\#_{N}$ (in bitesti). The number of observed successes is the number of 1 s in varname (in bitest) or $\#_{\text {succ }}$ (in bitesti). varname must contain only $0 \mathrm{~s}, 1 \mathrm{~s}$, and missing.
bitesti is the immediate form of bitest; see [U] 19 Immediate commands for a general introduction to immediate commands.

## Quick start

Exact test for probability of success $(a=1)$ is 0.4
bitest a = . 4
With additional exact probabilities
bitest a = .4, detail
Exact test that the probability of success is 0.46 , given 22 successes in 74 trials bitesti 7422.46

Statistics $>$ Summaries, tables, and tests $>$ Classical tests of hypotheses $>$ Binomial probability test calculator

## Syntax

Binomial probability test
bitest varname $=\#_{p}$ [if] [in] [weight] [, detail]

Immediate form of binomial probability test
bitesti $\#_{N} \#_{\text {succ }} \#_{p}[$, detail $]$
by and collect are allowed with bitest; see [U] 11.1.10 Prefix commands.
fweights are allowed with bitest; see [U] 11.1.6 weight.

## Option

## Remarks and examples

Remarks are presented under the following headings:
bitest
bitesti

## bitest

> Example 1
We test 15 university students for high levels of one measure of visual quickness which, from other evidence, we believe is present in $30 \%$ of the nonuniversity population. Included in our data is quick, taking on the values 1 ("success") or 0 ("failure") depending on the outcome of the test.

```
. use https://www.stata-press.com/data/r18/quick
. bitest quick == 0.3
Binomial probability test
\begin{tabular}{r|rrrrr} 
Variable & N & Observed \(k\) & Expected \(k\) & Assumed p & Observed p \\
\hline quick & 15 & 7 & 4.5 & 0.30000 & 0.46667
\end{tabular}
    Pr(k >= 7) = 0.131143 (one-sided test)
    Pr}(\textrm{k}<=7)=0.949987 (one-sided test
    Pr}(\textrm{k}<=1\mathrm{ or k >= 7) = 0.166410 (two-sided test)
```

The first part of the output reveals that, assuming a true probability of success of 0.3 , the expected number of successes is 4.5 and that we observed seven. Said differently, the assumed frequency under the null hypothesis $H_{0}$ is 0.3 , and the observed frequency is 0.47 .

The first line under the table is a one-sided test; it is the probability of observing seven or more successes conditional on $p=0.3$. It is a test of $H_{0}: p=0.3$ versus the alternative hypothesis $H_{\mathrm{A}}: p>0.3$. Said in English, the alternative hypothesis is that more than $30 \%$ of university students score at high levels on this test of visual quickness. The $p$-value for this hypothesis test is 0.13 .

The second line under the table is a one-sided test of $H_{0}$ versus the opposite alternative hypothesis $H_{\mathrm{A}}: p<0.3$.

The third line is the two-sided test. It is a test of $H_{0}$ versus the alternative hypothesis $H_{\mathrm{A}}: p \neq 0.3$.

## Technical note

The $p$-value of a hypothesis test is the probability (calculated assuming $H_{0}$ is true) of observing any outcome as extreme or more extreme than the observed outcome, with extreme meaning in the direction of the alternative hypothesis. In example 1 , the outcomes $k=8,9, \ldots, 15$ are clearly "more extreme" than the observed outcome $k_{\text {obs }}=7$ when considering the alternative hypothesis $H_{\mathrm{A}}: p \neq 0.3$. However, outcomes with only a few successes are also in the direction of this alternative hypothesis. For two-sided hypotheses, outcomes with $k$ successes are considered "as extreme or more extreme" than the observed outcome $k_{\text {obs }}$ if $\operatorname{Pr}(k) \leq \operatorname{Pr}\left(k_{\text {obs }}\right)$. Here $\operatorname{Pr}(k=0)$ and $\operatorname{Pr}(k=1)$ are both less than $\operatorname{Pr}(k=7)$, so they are included in the two-sided $p$-value.

The detail option allows you to see the probability (assuming that $H_{0}$ is true) of the observed successes $(k=7)$ and the probability of the boundary point $(k=1)$ of the opposite tail used for the two-sided $p$-value.

```
. bitest quick == 0.3, detail
Binomial probability test
\begin{tabular}{|c|c|c|c|c|}
\hline Variable & N Obse & ved k Expected k & Assumed p & Observed p \\
\hline quick & 15 & \(7 \quad 4.5\) & 0.30000 & 0.46667 \\
\hline \(\operatorname{Pr}(\mathrm{k}>=7)\) & \(=0.131143\) & (one-sided test) & & \\
\hline \(\operatorname{Pr}(\mathrm{k}<=7)\) & \(=0.949987\) & (one-sided test) & & \\
\hline \(\operatorname{Pr}(\mathrm{k}<=1\) or & \(=0.166410\) & (two-sided test) & & \\
\hline \(\operatorname{Pr}(\mathrm{k}==7\) ) & \(=0.081130\) & (observed) & & \\
\hline \(\operatorname{Pr}(\mathrm{k}==2)\) & \(=0.091560\) & & & \\
\hline \(\operatorname{Pr}(\mathrm{k}==1)\) & \(=0.030520\) & (opposite extreme) & & \\
\hline
\end{tabular}
```

Also shown is the probability of the point next to the boundary point. This probability, namely, $\operatorname{Pr}(k=2)=0.092$, is certainly close to the probability of the observed outcome $\operatorname{Pr}(k=7)=0.081$, so some people might argue that $k=2$ should be included in the two-sided $p$-value. Statisticians (at least some we know) would reply that the $p$-value is a precisely defined concept and that this is an arbitrary "fuzzification" of its definition. When you compute exact $p$-values according to the precise definition of a $p$-value, your type I error is never more than what you say it is - so no one can criticize you for being anticonservative. Including the point $k=2$ is being overly conservative because it makes the $p$-value larger yet. But it is your choice; being overly conservative, at least in statistics, is always safe. Know that bitest and bitesti always keep to the precise definition of a $p$-value, so if you wish to include this extra point, you must do so by hand or by using the $r()$ stored results; see Stored results below.

## bitesti

## Example 2

The binomial test is a function of two statistics and one parameter: $N$, the number of observations; $k_{\text {obs }}$, the number of observed successes; and $p$, the assumed probability of a success on a trial. For instance, in a city of $N=2,500,000$, we observe $k_{\text {obs }}=36$ cases of a particular disease when the population rate for the disease is $p=0.00001$.

| N | Observed k | Expected |  | Assumed p | Observed p |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2,500,000 | 36 |  | 25 | 0.00001 | 0.00001 |
| $\operatorname{Pr}(\mathrm{k}>=36)$ |  | 0.022458 |  | -sided te |  |
| $\operatorname{Pr}(\mathrm{k}<=36)$ | $=$ | 0.985448 |  | -sided test) |  |
| $\operatorname{Pr}(\mathrm{k}<=14$ or | $\mathrm{k}>=36)=$ | 0.034859 |  | -sided tes |  |

## Stored results

bitest and bitesti store the following in $r()$ :
Scalars

```
r(N) number }N\mathrm{ of trials
    r(P_p) assumed probability p of success
    r(k) observed number k of successes
    r(p_l) lower one-sided p-value
    r(p_u) upper one-sided p-value
    r(p) two-sided p-value
    r(k_opp) opposite extreme k
    r(P_k) probability of observed k (detail only)
    r(P_oppk) probability of opposite extreme k (detail only)
    r(k_nopp) b next to opposite extreme (detail only)
    r(P_noppk) probability of k next to opposite extreme (detail only)
```

## Methods and formulas

Let $N, k_{\text {obs }}$, and $p$ be, respectively, the number of observations, the observed number of successes, and the assumed probability of success on a trial. The expected number of successes is $N p$, and the observed probability of success on a trial is $k_{\text {obs }} / N$.
bitest and bitesti compute exact $p$-values based on the binomial distribution. The upper one-sided $p$-value is

$$
\operatorname{Pr}\left(k \geq k_{\mathrm{obs}}\right)=\sum_{m=k_{\mathrm{obs}}}^{N}\binom{N}{m} p^{m}(1-p)^{N-m}
$$

The lower one-sided $p$-value is

$$
\operatorname{Pr}\left(k \leq k_{\mathrm{obs}}\right)=\sum_{m=0}^{k_{\mathrm{obs}}}\binom{N}{m} p^{m}(1-p)^{N-m}
$$

If $k_{\text {obs }} \geq N p$, the two-sided $p$-value is

$$
\operatorname{Pr}\left(k \leq k_{\text {opp }} \text { or } k \geq k_{\text {obs }}\right)
$$

where $k_{\text {opp }}$ is the largest number $\leq N p$ such that $\operatorname{Pr}\left(k=k_{\text {opp }}\right) \leq \operatorname{Pr}\left(k=k_{\text {obs }}\right)$. If $k_{\text {obs }}<N p$, the two-sided $p$-value is

$$
\operatorname{Pr}\left(k \leq k_{\mathrm{obs}} \text { or } k \geq k_{\mathrm{opp}}\right)
$$

where $k_{\text {opp }}$ is the smallest number $\geq N p$ such that $\operatorname{Pr}\left(k=k_{\text {opp }}\right) \leq \operatorname{Pr}\left(k=k_{\text {obs }}\right)$.

## Title

bootstrap - Bootstrap sampling and estimation

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

bootstrap performs nonparametric bootstrap estimation of specified statistics (or expressions) for a Stata command or a user-written program. Statistics are bootstrapped by resampling the data in memory with replacement. bootstrap is designed for use with nonestimation commands, functions of coefficients, or user-written programs. To bootstrap coefficients, we recommend using the vce(bootstrap) option when allowed by the estimation command.

## Quick start

Bootstrap the mean of v1 returned by summarize in $r$ (mean) bootstrap mean=r(mean): summarize v1

Bootstrap the statistic $r$ (mystat) returned by program myprog1 bootstrap stat=r(mystat): myprog1 v1

Same as above, but use 100 replications
bootstrap stat=r(mystat), reps(100): myprog1 v1
Same as above, and save the results from each replication in mydata.dta bootstrap stat=r(mystat), reps(100) saving(mydata): myprog1 v1

Bootstrap a difference in coefficients estimated by regress

```
bootstrap diff=(_b[x2]-_b[x1]): regress y x1 x2 x3
```

Bootstrap the coefficients stored in e(b) by myprog2

```
bootstrap _b: myprog2 y x1 x2 x3
```

Same as above, but with bootstrap samples taken independently within strata identified by svar bootstrap _b, strata(svar): myprog2 y x1 x2 x3

Resample clusters defined by cvar and create newcvar identifying resampled clusters bootstrap _b, cluster(cvar) idcluster(newcvar): myprog2 y x1 x2 x3

Description
perform \# bootstrap replications; default is reps (50)
variables identifying strata
draw samples of size \#; default is $\_\mathrm{N}$
variables identifying resampling clusters
create new cluster ID variable
save results to filename; save statistics in double precision;
save results to filename every \# replications
compute acceleration for $\mathrm{BC}_{a}$ confidence intervals
adjust $\mathrm{BC} / \mathrm{BCa}$ confidence intervals for ties
use MSE formula for variance estimation
set confidence level; default is level (95)
suppress table of results
suppress table header suppress table legend
display the full table legend
suppress replication dots
display dots every \# replications
display any output from command
trace command
use text as title for bootstrap results
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
display coefficient table in exponentiated form
do not drop observations
do not warn when e(sample) is not set
do not check for weights or svy commands; seldom used identify invalid results
set random-number seed to \#

ID variable for groups within cluster ()
options for jackknife; see [R] jackknife
display legend instead of statistics
command is any command that follows standard Stata syntax. weights are not allowed in command. collect and svy are allowed; see [U] 11.1.10 Prefix commands. group(), jackknifeopts(), and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

| exp_list contains | (name: elist) elist |
| :---: | :---: |
|  | eexp |
| elist contains | $\begin{aligned} & \text { newvar }=(\exp ) \\ & (\text { exp }) \end{aligned}$ |

|  | _se |
|  | _se [] |
| eqno is | \# \# |
|  | name |

$\exp$ is a standard Stata expression; see [U] 13 Functions and expressions.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.

## Options

$\qquad$ Main
reps (\#) specifies the number of bootstrap replications to be performed. The default is 50. A total of $50-200$ replications are generally adequate for estimates of standard error and thus are adequate for normal-approximation confidence intervals; see Mooney and Duval (1993, 11). Estimates of confidence intervals using the percentile or bias-corrected methods typically require 1,000 or more replications.

## Options

strata (varlist) specifies the variables that identify strata. If this option is specified, bootstrap samples are taken independently within each stratum.
size(\#) specifies the size of the samples to be drawn. The default is $\_$N, meaning to draw samples of the same size as the data. If specified, \# must be less than or equal to the number of observations within strata().

If cluster() is specified, the default size is the number of clusters in the original dataset. For unbalanced clusters, resulting sample sizes will differ from replication to replication. For cluster sampling, \# must be less than or equal to the number of clusters within strata().
cluster (varlist) specifies the variables that identify resampling clusters. If this option is specified, the sample drawn during each replication is a bootstrap sample of clusters.
idcluster (newvar) creates a new variable containing a unique identifier for each resampled cluster.
This option requires that cluster() also be specified.
saving ( filename [, suboptions]) creates a Stata data file (.dta file) consisting of (for each statistic in exp_list) a variable containing the replicates.
double specifies that the results for each replication be saved as doubles, meaning 8-byte reals. By default, they are saved as floats, meaning 4-byte reals. This option may be used without the saving() option to compute the variance estimates by using double precision.
every (\#) specifies that results be written to disk every \#th replication. every () should be specified only in conjunction with saving () when command takes a long time for each replication. This option will allow recovery of partial results should some other software crash your computer. See [ P$]$ postfile.
replace specifies that filename be overwritten if it exists. This option does not appear in the dialog box.
bca specifies that bootstrap estimate the acceleration of each statistic in exp_list. This estimate is used to construct $\mathrm{BC}_{a}$ confidence intervals. Type estat bootstrap, bca to display the $\mathrm{BC}_{a}$ confidence interval generated by the bootstrap command.
ties specifies that bootstrap adjust for ties in the replicate values when computing the median bias used to construct BC and BCa confidence intervals.
mse specifies that bootstrap compute the variance by using deviations of the replicates from the observed value of the statistics based on the entire dataset. By default, bootstrap computes the variance by using deviations from the average of the replicates.

## Reporting

level(\#); see [R] Estimation options.
notable suppresses the display of the table of results.
noheader suppresses the display of the table header. This option implies nolegend. This option may also be specified when replaying estimation results.
nolegend suppresses the display of the table legend. This option may also be specified when replaying estimation results.
verbose specifies that the full table legend be displayed. By default, coefficients and standard errors are not displayed. This option may also be specified when replaying estimation results.
nodots and dots(\#) specify whether to display replication dots. By default, one dot character is displayed for each successful replication. An " x " is displayed if command returns an error or if any value in exp_list is missing. You can also control whether dots are displayed using set dots; see [R] set.
nodots suppresses display of the replication dots.
dots (\#) displays dots every \# replications. dots (0) is a synonym for nodots.
noisily specifies that any output from command be displayed. This option implies the nodots option.
trace causes a trace of the execution of command to be displayed. This option implies the noisily option.
title (text) specifies a title to be displayed above the table of bootstrap results. The default title is the title stored in e(title) by an estimation command, or if e(title) is not filled in, Bootstrap results is used. title() may also be specified when replaying estimation results.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% $\% m t$ ), and nolstretch; see [R] Estimation options.
eform_option causes the coefficient table to be displayed in exponentiated form; see $[\mathrm{R}]$ eform_option.
command determines which of the following are allowed (eform(string) and eform are always allowed):

| eform_option | Description |
| :--- | :--- |
| eform (string) | use string for the column title |
| eform | exponentiated coefficient, string is exp (b) |
| hr | hazard ratio, string is Haz. ratio |
| shr | subhazard ratio, string is SHR |
| $\underline{\mathrm{irr}}$ | incidence-rate ratio, string is IRR <br> or |
| $\underline{\mathrm{rrr}}$ | odds ratio, string is Odds ratio <br> relative-risk ratio, string is RRR |

Advanced
nodrop prevents observations outside e(sample) and the if and in qualifiers from being dropped before the data are resampled.
nowarn suppresses the display of a warning message when command does not set e(sample).
force suppresses the restriction that command not specify weights or be a svy command. This is a rarely used option. Use it only if you know what you are doing.
reject (exp) identifies an expression that indicates when results should be rejected. When exp is true, the resulting values are reset to missing values.
seed(\#) sets the random-number seed. Specifying this option is equivalent to typing the following command prior to calling bootstrap:
. set seed \#
The following options are available with bootstrap but are not shown in the dialog box:
group (varname) re-creates varname containing a unique identifier for each group across the resampled clusters. This option requires that idcluster() also be specified.
This option is useful for maintaining unique group identifiers when sampling clusters with replacement. Suppose that cluster 1 contains 3 groups. If the idcluster (newclid) option is specified and cluster 1 is sampled multiple times, newclid uniquely identifies each copy of cluster 1 . If group (newgroupid) is also specified, newgroupid uniquely identifies each copy of each group.
jackknifeopts (jkopts) identifies options that are to be passed to jackknife when it computes the acceleration values for the $\mathrm{BC}_{a}$ confidence intervals; see [R] jackknife. This option requires the bca option and is mostly used for passing the eclass, rclass, or n(\#) option to jackknife.
coeflegend; see [R] Estimation options.

## Introduction

Using bootstrap
Regression coefficients
Expressions
Combining bootstrap datasets
A note about macros
Achieved significance level
Bootstrapping a ratio
Warning messages and e(sample)
Bootstrapping statistics from data with a complex structure

## Introduction

With few assumptions, bootstrapping provides a way of estimating standard errors and other measures of statistical precision (Efron 1979; Efron and Stein 1981; Efron 1982; Efron and Tibshirani 1986; Efron and Tibshirani 1993; also see Davison and Hinkley [1997]; Guan [2003]; Mooney and Duval [1993]; Poi [2004]; and Stine [1990]). It provides a way to obtain such measures when no formula is otherwise available or when available formulas make inappropriate assumptions. Cameron and Trivedi (2022, chap. 12) discuss many bootstrapping topics and demonstrate how to do them in Stata.

To illustrate bootstrapping, suppose that you have a dataset containing $N$ observations and an estimator that, when applied to the data, produces certain statistics. You draw, with replacement, $N$ observations from the $N$-observation dataset. In this random drawing, some of the original observations will appear once, some more than once, and some not at all. Using the resampled dataset, you apply the estimator and collect the statistics. This process is repeated many times; each time, a new random sample is drawn and the statistics are recalculated.

This process builds a dataset of replicated statistics. From these data, you can calculate the standard error by using the standard formula for the sample standard deviation

$$
\widehat{\mathrm{se}}=\left\{\frac{1}{k-1} \sum\left(\widehat{\theta}_{i}-\bar{\theta}\right)^{2}\right\}^{1 / 2}
$$

where $\widehat{\theta}_{i}$ is the statistic calculated using the $i$ th bootstrap sample and $k$ is the number of replications. This formula gives an estimate of the standard error of the statistic, according to Hall and Wilson (1991). Although the average, $\bar{\theta}$, of the bootstrapped estimates is used in calculating the standard deviation, it is not used as the estimated value of the statistic itself. Instead, the original observed value of the statistic, $\widehat{\theta}$, is used, meaning the value of the statistic computed using the original $N$ observations.

You might think that $\bar{\theta}$ is a better estimate of the parameter than $\widehat{\theta}$, but it is not. If the statistic is biased, bootstrapping exaggerates the bias. In fact, the bias can be estimated as $\bar{\theta}-\widehat{\theta}$ (Efron 1982, 33). Knowing this, you might be tempted to subtract this estimate of bias from $\widehat{\theta}$ to produce an unbiased statistic. The bootstrap bias estimate has an indeterminate amount of random error, so this unbiased estimator may have greater mean squared error than the biased estimator (Mooney and Duval 1993; Hinkley 1978). Thus, $\widehat{\theta}$ is the best point estimate of the statistic.

The logic behind the bootstrap is that all measures of precision come from a statistic's sampling distribution. When the statistic is estimated on a sample of size $N$ from some population, the sampling distribution tells you the relative frequencies of the values of the statistic. The sampling distribution, in turn, is determined by the distribution of the population and the formula used to estimate the statistic.

Sometimes the sampling distribution can be derived analytically. For instance, if the underlying population is distributed normally and you calculate means, the sampling distribution for the mean is also normal but has a smaller variance than that of the population. In other cases, deriving the sampling distribution is difficult, such as when means are calculated from nonnormal populations. Sometimes, as in the case of means, it is not too difficult to derive the sampling distribution as the sample size goes to infinity $(N \rightarrow \infty)$. However, such asymptotic distributions may not perform well when applied to finite samples.

If you knew the population distribution, you could obtain the sampling distribution by simulation: you could draw random samples of size $N$, calculate the statistic, and make a tally. Bootstrapping does precisely this, but it uses the observed distribution of the sample in place of the true population distribution. Thus, the bootstrap procedure hinges on the assumption that the observed distribution is a good estimate of the underlying population distribution. In return, the bootstrap produces an estimate, called the bootstrap distribution, of the sampling distribution. From this, you can estimate the standard error of the statistic, produce confidence intervals, etc.

The accuracy with which the bootstrap distribution estimates the sampling distribution depends on the number of observations in the original sample and the number of replications in the bootstrap. A crudely estimated sampling distribution is adequate if you are going to extract, say, only a standard error. A better estimate is needed if you want to use the 2.5 th and 97.5 th percentiles of the distribution to produce a $95 \%$ confidence interval. To extract many features simultaneously about the distribution, an even better estimate is needed. Generally, replications on the order of 1,000 produce very good estimates, but only $50-200$ replications are needed for estimates of standard errors. See Poi (2004) for a method to choose the number of bootstrap replications.

## Using bootstrap

## Typing

. bootstrap exp_list, reps(\#): command
executes command multiple times, bootstrapping the statistics in exp_list by resampling observations (with replacement) from the data in memory \# times. This method is commonly referred to as the nonparametric bootstrap.
command defines the statistical command to be executed. Most Stata commands and user-written programs can be used with bootstrap, as long as they follow standard Stata syntax; see [U] 11 Language syntax. If the bca option is supplied, command must also work with jackknife; see [R] jackknife. The by prefix may not be part of command.
exp_list specifies the statistics to be collected from the execution of command. If command changes the contents in e(b), exp_list is optional and defaults to _b.

Because bootstrapping is a random process, if you want to be able to reproduce results, set the random-number seed by specifying the seed(\#) option or by typing
. set seed \#
where \# is a seed of your choosing, before running bootstrap; see [R] set seed.

## Regression coefficients

## - Example 1

Let's say that we wish to compute bootstrap estimates for the standard errors of the coefficients from the following regression:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight gear foreign
```

| Source | SS | df | MS |
| ---: | :---: | ---: | :---: |

To run the bootstrap, we simply prefix the above regression command with the bootstrap command (specifying its options before the colon separator). We must set the random-number seed before calling bootstrap.

| . bootstrap, reps(100) seed(1): regress mpg weight gear foreign (running regress on estimation sample) |  |  |

The displayed confidence interval is based on the assumption that the sampling (and hence bootstrap) distribution is approximately normal (see Methods and formulas below). Because this confidence interval is based on the standard error, it is a reasonable estimate if normality is approximately true, even for a few replications. Other types of confidence intervals are available after bootstrap; see $[R]$ bootstrap postestimation.

We could instead supply names to our expressions when we run bootstrap. For example,

```
. bootstrap diff=(_b[weight]-_b[gear]): regress mpg weight gear foreign
```

would bootstrap a statistic, named diff, equal to the difference between the coefficients on weight and gear_ratio.

## - Technical note

regress, like many estimation commands, allows the vce (bootstrap) option. For any estimation command that allows this option, we recommend using vce (bootstrap) over bootstrap because the estimation command automatically handles clustering and other model-specific details for you.

## Expressions

## > Example 2

When we use bootstrap, the list of statistics can contain complex expressions, as long as each expression is enclosed in parentheses. For example, to bootstrap the range of a variable $x$, we could type

```
. bootstrap range=(r(max)-r(min)), reps(1000): summarize x
```

Of course, we could also bootstrap the minimum and maximum and later compute the range.

```
. bootstrap max=r(max) min=r(min), reps(1000) saving(mybs): summarize x
. use mybs, clear
(bootstrap: summarize)
. generate range = max - min
. bstat range, stat(19.5637501)
```

The difference between the maximum and minimum of x in the sample is 19.5637501 .
The stat () option to bstat specifies the observed value of the statistic (range) to be summarized. This option is useful when, as shown above, the statistic of ultimate interest is not specified directly to bootstrap but instead is calculated by other means.

Here the observed values of $r(\max )$ and $r(\min )$ are stored as characteristics of the dataset created by bootstrap and are thus available for retrieval by bstat; see [R] bstat. The observed range, however, is unknown to bstat, so it must be specified.

## Combining bootstrap datasets

You can combine two datasets from separate runs of bootstrap by using append (see [D] append) and then get the bootstrap statistics for the combined datasets by running bstat. The runs must have been performed independently (having different starting random-number seeds), and the original dataset, command, and bootstrap statistics must have been all the same.

## A note about macros

In example 2, we executed the command

```
. bootstrap max=r(max) min=r(min), reps(1000) saving(mybs): summarize x
```

We did not enclose $r(\max )$ and $r(\min )$ in single quotes, as we would in most other contexts, because it would not produce what was intended:

```
. bootstrap 'r(max)' 'r(min)', reps(1000) saving(mybs): summarize x
```

To understand why, note that ' $r(\max )$ ', like any reference to a local macro, will evaluate to a literal string containing the contents of $r(\max )$ before bootstrap is even executed. Typing the command above would appear to Stata as if we had typed

```
. bootstrap 14.5441234 33.4393293, reps(1000) saving(mybs): summarize x
```

Even worse, the current contents of $r(\min )$ and $r(\max )$ could be empty, producing an even more confusing result. To avoid this outcome, refer to statistics by name (for example, $r(\max )$ ) and not by value (for example, ' $r(\max )$ ').

## Achieved significance level

## > Example 3

Suppose that we wish to estimate the achieved significance level (ASL) of a test statistic by using the bootstrap. ASL is another name for $p$-value. An example is

$$
\mathrm{ASL}=\operatorname{Pr}\left(\widehat{\theta}^{*} \geq \widehat{\theta} \mid H_{0}\right)
$$

for an upper-tailed, alternative hypothesis, where $H_{0}$ denotes the null hypothesis, $\widehat{\theta}$ is the observed value of the test statistic, and $\widehat{\theta}^{*}$ is the random variable corresponding to the test statistic, assuming that $H_{0}$ is true.

Here we will compare the mean miles per gallon ( mpg ) between foreign and domestic cars by using the two-sample $t$ test with unequal variances. The following results indicate the $p$-value to be 0.0034 for the two-sided test using Satterthwaite's approximation. Thus, assuming that mean mpg is the same for foreign and domestic cars, we would expect to observe a $t$ statistic more extreme (in absolute value) than 3.1797 in about $0.3 \%$ of all possible samples of the type that we observed. Thus, we have evidence to reject the null hypothesis that the means are equal.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. ttest mpg, by(foreign) unequal
Two-sample \(t\) test with unequal variances
```

| Group | Obs | Mean | Std. err | Std. dev. | [95\% conf | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Domestic | 52 | 19.82692 | . 657777 | 4.743297 | 18.50638 | 21.14747 |
| Foreign | 22 | 24.77273 | 1.40951 | 6.611187 | 21.84149 | 27.70396 |
| Combined | 74 | 21.2973 | . 6725511 | 5.785503 | 19.9569 | 22.63769 |
| diff |  | -4.945804 | 1.555438 |  | -8.120053 | -1.771556 |
| diff $=$ mean(Domestic) - mean(Foreign) $t=-3.1797$ <br> H0: $\operatorname{diff}=0$ Satterthwaite's degrees of freedom $=30.5463$  <br> Ha: diff < 0 Ha: diff $!=0$ $H a: \operatorname{diff}>0$ <br> $\operatorname{Pr}(T<t)=0.0017$ $\operatorname{Pr}(\|T\|>\|t\|)=0.0034$ $\operatorname{Pr}(T>t)=0.9983$ |  |  |  |  |  |  |
|  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |

We also place the value of the test statistic in a scalar for later use.

```
. scalar tobs = r(t)
```

Efron and Tibshirani $(1993,224)$ describe an alternative to Satterthwaite's approximation that estimates the ASL by bootstrapping the statistic from the test of equal means. Their idea is to recenter the two samples to the combined sample mean so that the data now conform to the null hypothesis but that the variances within the samples remain unchanged.

```
. summarize mpg, meanonly
. scalar omean = r(mean)
. summarize mpg if foreign==O, meanonly
. replace mpg = mpg - r(mean) + scalar(omean) if foreign==0
variable mpg was int now float
(52 real changes made)
. summarize mpg if foreign==1, meanonly
. replace mpg = mpg - r(mean) + scalar(omean) if foreign==1
(22 real changes made)
. sort foreign
```

. by foreign: summarize mpg
-> foreign = Domestic

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| mpg | 52 | 21.2973 | 4.743297 | 13.47037 | 35.47038 |

| -> foreign $=$ Foreign |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Variable |  | Obs | Mean | Std. dev. | Min | Max |
| mpg | 22 | 21.2973 | 6.611187 | 10.52457 | 37.52457 |  |

Each sample (foreign and domestic) is a stratum, so the bootstrapped samples must have the same number of foreign and domestic cars as the original dataset. This requirement is facilitated by the strata() option to bootstrap. By typing the following, we bootstrap the test statistic using the modified dataset and save the values in bsauto2.dta:

```
. keep mpg foreign
. set seed 1
. bootstrap t=r(t), rep(1000) strata(foreign) saving(bsauto2) nodots: ttest mpg,
> by(foreign) unequal
warning: ttest does not set e(sample), so no observations will be excluded
    from the resampling because of missing values or other reasons. To
    exclude observations, press Break, save the data, drop any
    observations that are to be excluded, and rerun bootstrap.
Bootstrap results
Number of strata = 2 Number of obs = 74
Replications = 1,000
    Command: ttest mpg, by(foreign) unequal
        t: r(t)
\begin{tabular}{l|cccccr}
\hline & \begin{tabular}{c} 
Observed \\
coefficient
\end{tabular} & \begin{tabular}{l} 
Bootstrap \\
std. err.
\end{tabular} & \(\mathbf{z}\) & \(\mathrm{P}>|\mathrm{z}|\) & \begin{tabular}{c} 
Normal-based \\
[95\% conf. interval]
\end{tabular} \\
\hline t & \(1.75 \mathrm{e}-07\) & 1.051867 & 0.00 & 1.000 & -2.061622 & 2.061622 \\
\hline
\end{tabular}
```

We can use the data in bsauto2.dta to estimate ASL via the fraction of bootstrap test statistics that are more extreme than 3.1797.

```
. use bsauto2, clear
(bootstrap: ttest)
. generate indicator = abs(t)>=abs(scalar(tobs))
. summarize indicator, meanonly
. display "ASLboot = " r(mean)
ASLboot = . }00
```

The result is $\mathrm{ASL}_{\mathrm{boot}}=0.004$. Assuming that the mean mpg is the same between foreign and domestic cars, we would expect to observe a $t$ statistic more extreme (in absolute value) than 3.1797 in about $0.4 \%$ of all possible samples of the type we observed. This finding is still strong evidence to reject the hypothesis that the means are equal.

## Bootstrapping a ratio

## > Example 4

Suppose that we wish to produce a bootstrap estimate of the ratio of two means. Because summarize stores results for only one variable, we must call summarize twice to compute the means. Actually, we could use collapse to compute the means in one call, but calling summarize twice is much faster. Thus, we will have to write a small program that will return the results we want.

We write the program below and save it to a file called ratio. ado (see [U] $\mathbf{1 7}$ Ado-files). Our program takes two variable names as input and saves them in the local macros y (first variable) and $x$ (second variable). It then computes one statistic: the mean of ' $y$ ' divided by the mean of ' $x$ '. This value is returned as a scalar in $r$ (ratio). ratio also returns the ratio of the number of observations used to the mean for each variable.

```
program myratio, rclass
    version 18.0 // (or version 18.5 for StataNow)
    args y x
    confirm var 'y'
    confirm var 'x'
    tempname ymean
    summarize 'y', meanonly
    scalar 'ymean' = r(mean)
    return scalar n_'y' = r(N)
    summarize 'x', meanonly
    return scalar n_'x' = r(N)
    return scalar ratio = 'ymean'/r(mean)
end
```

Remember to test any newly written commands before using them with bootstrap.

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. summarize price
\begin{tabular}{r|rrrrr} 
Variable & Obs & Mean & Std. dev. & Min & Max \\
\hline price & 74 & 6165.257 & 2949.496 & 3291 & 15906
\end{tabular}
. scalar mean1=r(mean)
. summarize weight
\begin{tabular}{r|rrrrr} 
Variable & Obs & Mean & Std. dev. & Min & Max \\
\hline weight & 74 & 3019.459 & 777.1936 & 1760 & 4840
\end{tabular}
. scalar mean2=r(mean)
. di scalar(mean1)/scalar(mean2)
2.0418412
. myratio price weight
. return list
scalars:
\[
\begin{aligned}
r(\text { ratio }) & =2.041841210168278 \\
r(\text { n_weight }) & =74 \\
r(\text { n_price }) & =74
\end{aligned}
\]
    r(ratio) = 2.041841210168278
    r(n_weight) = 74
        r(n_price) = 74
```

The results of running bootstrap on our program are

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. set seed 1
. bootstrap ratio=r(ratio), reps(1000) nowarn nodots: myratio price weight
Bootstrap results Number of obs = 74
Replications = 1,000
```

    Command: myratio price weight
        ratio: r(ratio)
    |  | Observed <br> coefficient | Bootstrap <br> std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | Normal-based <br> [95\% conf. interval] |  |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ratio | 2.041841 | .0953559 | 21.41 | 0.000 | 1.854947 | 2.228735 |

As mentioned previously, we should specify the saving() option if we wish to save the bootstrap dataset.

## Warning messages and e(sample)

bootstrap is not meant to be used with weighted calculations. bootstrap determines the presence of weights by parsing the prefixed command with standard syntax. However, commands like stcox and streg require that weights be specified in stset, and some user commands may allow weights to be specified by using an option instead of the standard syntax. Both cases pose a problem for bootstrap because it cannot determine the presence of weights under these circumstances. In these cases, we can only assume that you know what you are doing.
bootstrap does not know which variables of the dataset in memory matter to the calculation at hand. You can speed their execution by dropping unnecessary variables because, otherwise, they are included in each bootstrap sample.

You should thus drop observations with missing values. Leaving in missing values causes no problem in one sense because all Stata commands deal with missing values gracefully. It does, however, cause a statistical problem. Bootstrap sampling is defined as drawing, with replacement, samples of size $N$ from a set of $N$ observations. bootstrap determines $N$ by counting the number of observations in memory, not counting the number of nonmissing values on the relevant variables. The result is that too many observations are resampled; the resulting bootstrap samples, because they are drawn from a population with missing values, are of unequal sizes.

If the number of missing values relative to the sample size is small, this will make little difference. If you have many missing values, however, you should first drop the observations that contain them.

## > Example 5

To illustrate, we use the previous example but replace some of the values of price with missing values. The number of values of price used to compute the mean for each bootstrap is not constant. This is the purpose of the warning message.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. replace price = . if inlist(_n,1,3,5,7)
(4 real changes made, 4 to missing)
. set seed 1
. bootstrap ratio=r(ratio) np=r(n_price) nw=r(n_weight), reps(100) nodots:
> myratio price weight
warning: myratio does not set e(sample), so no observations will be excluded
    from the resampling because of missing values or other reasons. To
    exclude observations, press Break, save the data, drop any
    observations that are to be excluded, and rerun bootstrap.
Bootstrap results Number of obs = 74
                                    Replications = 100
    Command: myratio price weight
        ratio: r(ratio)
            np: r(n_price)
            nw: r(n_weight)
\begin{tabular}{r|rrrrrr}

\hline
\end{tabular}
```

## Bootstrapping statistics from data with a complex structure

Here we describe how to bootstrap statistics from data with a complex structure, for example, longitudinal or panel data, or matched data. bootstrap, however, is not designed to work with complex survey data. It is important to include all necessary information about the structure of the data in the bootstrap syntax to obtain correct bootstrap estimates for standard errors and confidence intervals.
bootstrap offers several options identifying the specifics of the data. These options are strata(), cluster(), idcluster(), and group(). The usage of strata() was described in example 3 above. Below, we demonstrate several examples that require specifying the other three options.

## > Example 6

Suppose that auto.dta in example 1 above are clustered by rep78. We want to obtain bootstrap estimates for the standard errors of the difference between the coefficients on weight and gear_ratio, taking into account clustering.

We supply the cluster (rep78) option to bootstrap to request resampling from clusters rather than from observations in the dataset.

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. keep if rep78<.
(5 observations deleted)
. bootstrap diff=(_b[weight]-_b[gear]), seed(1) cluster(rep78): regress mpg
> weight gear foreign
(running regress on estimation sample)
Bootstrap replications (50): .........10..........20...........30...........40........
> ..50 done
Linear regression Number of obs = 69
                                    Replications = 50
    Command: regress mpg weight gear foreign
        diff: _b[weight]-_b[gear]
                            (Replications based on 5 clusters in rep78)
\begin{tabular}{c|cccccr}
\hline & \begin{tabular}{c} 
Observed \\
coefficient
\end{tabular} & \begin{tabular}{l} 
Bootstrap \\
std. err.
\end{tabular} & z & \(\mathrm{P}>|\mathrm{z}|\) & \begin{tabular}{c}
\multicolumn{2}{c}{\begin{tabular}{c} 
Normal-based \\
[95\% conf. interval]
\end{tabular}} \\
\hline diff
\end{tabular}\(-1.910396\) & 2.538558 \\
\hline
\end{tabular}
```

We drop missing values in rep78 before issuing the command because bootstrap does not allow missing values in cluster(). See the section above about using bootstrap when variables contain missing values.

We can also obtain these same results by using the following syntax:

```
. bootstrap diff=(_b[weight]-_b[gear]), seed(1): regress mpg weight gear foreign,
> vce(cluster rep78)
```

When only clustered information is provided to the command, bootstrap can pick up the vce (cluster clustvar) option from the main command and use it to resample from clusters.

## > Example 7

Suppose now that we have matched data and want to use bootstrap to obtain estimates of the standard errors of the exponentiated difference between two coefficients (or, equivalently, the ratio of two odds ratios) estimated by clogit. Consider the example of matched case-control data on birthweight of infants described in example 2 of $[R]$ clogit.

The infants are paired by being matched on mother's age. All groups, defined by the pairid variable, have $1: 1$ matching. clogit requires that the matching information, pairid, be supplied to the group() (or, equivalently, strata()) option to be used in computing the parameter estimates. Because the data are matched, we need to resample from groups rather than from the whole dataset. However, simply supplying the grouping variable pairid in cluster() is not enough with bootstrap, as it is with clustered data.

```
. use https://www.stata-press.com/data/r18/lowbirth2, clear
(Applied Logistic Regression, Hosmer \& Lemeshow)
. bootstrap ratio=exp(_b[smoke]-_b[ptd]), seed(1) cluster(pairid): clogit low
> lwt smoke ptd ht ui i.race, group(pairid)
(running clogit on estimation sample)
Bootstrap replications (50): ..........10..........20...........30........... \(40 . .\).
> .. 50 done
Bootstrap results Number of obs = 112
Replications \(=50\)
    Command: clogit low lwt smoke ptd ht ui i.race, group(pairid)
        ratio: \(\exp \left(\_b[s m o k e]-\_b[p t d]\right)\)
                            (Replications based on 56 clusters in pairid)
\begin{tabular}{r|cccccc}
\hline & \begin{tabular}{c} 
Observed \\
coefficient
\end{tabular} & \begin{tabular}{l} 
Bootstrap \\
std. err.
\end{tabular} & \(\mathbf{z}\) & \(\mathrm{P}>|\mathrm{z}|\) & \begin{tabular}{c} 
Normal-based \\
[95\% conf. interval]
\end{tabular} \\
\hline ratio & .6654095 & 2.043274 & 0.33 & 0.745 & -3.339334 & 4.670153 \\
\hline
\end{tabular}
```

For the syntax above, imagine that the first pair was sampled twice during a replication. Then, the bootstrap sample has four subjects with pairid equal to one, which clearly violates the original 1:1 matching design. As a result, the estimates of the coefficients obtained from this bootstrap sample will be incorrect.

Therefore, in addition to resampling from groups, we need to ensure that resampled groups are uniquely identified in each of the bootstrap samples. The idcluster (newcluster) option is designed for this. It requests that at each replication bootstrap create the new variable, newcluster, containing unique identifiers for all resampled groups. Thus, to make sure that the correct matching is preserved during each replication, we need to specify the grouping variable in cluster(), supply a variable name to idcluster(), and use this variable as the grouping variable with clogit, as we demonstrate below.

Note the difference between the estimates of the bootstrap standard error for the two specifications of the bootstrap syntax.

## - Technical note

Similarly, when you have panel (longitudinal) data, all resampled panels must be unique in each of the bootstrap samples to obtain correct bootstrap estimates of statistics. Therefore, both cluster(panelvar) and idcluster(newpanelvar) must be specified with bootstrap, and i (newpanelvar) must be used with the main command. Moreover, you must clear the current xtset settings by typing xtset, clear before calling bootstrap.

## > Example 8

Continuing with our birthweight data, suppose that we have more information about doctors supervising women's pregnancies. We believe that the data on the pairs of infants from the same doctor may be correlated and want to adjust standard errors for possible correlation among the pairs. clogit offers the vce (cluster clustvar) option to do this.

Let's add a cluster variable to our dataset. One thing to keep in mind is that to use vce (cluster clustvar), groups in group() must be nested within clusters.

```
. use https://www.stata-press.com/data/r18/lowbirth2, clear
(Applied Logistic Regression, Hosmer & Lemeshow)
. set seed 12345
. by pairid, sort: egen byte doctor = total(int(2*runiform()+1)*(_n == 1))
. clogit low lwt smoke ptd ht ui i.race, group(pairid) vce(cluster doctor)
Iteration 0: Log pseudolikelihood = -26.768693
Iteration 1: Log pseudolikelihood = -25.810476
Iteration 2: Log pseudolikelihood = -25.794296
Iteration 3: Log pseudolikelihood = -25.794271
Iteration 4: Log pseudolikelihood = -25.794271
Conditional (fixed-effects) logistic regression Number of obs = 112
Wald chi2(1) = .
Prob > chi2 = .
Pseudo R2 = 0.3355
(Std. err. adjusted for 2 clusters in doctor)
```

| low | Coefficient | Robust std. err. | z | $P>\|z\|$ | [95\% conf | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

To obtain correct bootstrap standard errors of the exponentiated difference between the two coefficients in this example, we need to make sure that both resampled clusters and groups within resampled clusters are unique in each of the bootstrap samples. To achieve this, bootstrap needs the information about clusters in cluster(), the variable name of the new identifier for clusters in idcluster(), and the information about groups in group(). We demonstrate the corresponding syntax of bootstrap below.

```
. bootstrap ratio=exp(_b[smoke]-_b[ptd]), seed(1) cluster(doctor)
> idcluster(uidoctor) group(pairid): clogit low lwt smoke ptd ht ui i.race,
> group(pairid)
(running clogit on estimation sample)
Bootstrap replications (50): .........10.........20..........30...........40.
> .. 50 done
Bootstrap results Number of obs = 112
Replications = 50
    Command: clogit low lwt smoke ptd ht ui i.race, group(pairid)
        ratio: exp(_b[smoke]-_b[ptd])
                            (Replications based on 2 clusters in doctor)
\begin{tabular}{c|cccccc}
\hline & \begin{tabular}{c} 
Observed \\
coefficient
\end{tabular} & \begin{tabular}{c} 
Bootstrap \\
std. err.
\end{tabular} & z & \(\mathrm{P}>|\mathrm{z}|\) & \begin{tabular}{c} 
Normal-based \\
[95\% conf. interval]
\end{tabular} \\
\hline ratio & .6654095 & .1459234 & 4.56 & 0.000 & .3794048 & .9514142 \\
\hline
\end{tabular}
```

In the above syntax, although we specify group (pairid) with clogit, it is not the group identifiers of the original pairid variable that are used to compute parameter estimates from bootstrap samples. The way bootstrap works is that, at each replication, the clusters defined by doctor are resampled and the new variable, uidoctor, uniquely identifying resampled clusters is created. After that, another new variable uniquely identifying the (uidoctor, group) combination is created and renamed to have the same name as the grouping variable, pairid. This newly defined grouping variable is then used by clogit to obtain the parameter estimates from this bootstrap sample of clusters. After all replications are performed, the original values of the grouping variable are restored.

## Technical note

The same logic must be used when running bootstrap with commands designed for panel (longitudinal) data that allow specifying the cluster (clustervar) option. To ensure that the combination of (clustervar, panelvar) values are unique in each of the bootstrap samples, cluster (clustervar), idcluster (newclustervar), and group (panelvar) must be specified with bootstrap, and i (panelvar) must be used with the main command.

## - Technical note

When the bootstrap prefix is used with a user-defined program and when the expression list is _b, bootstrap calls
set coeftabresults off
before entering the replication loop to prevent Stata from performing unnecessary calculations. This means that, provided option noisily is not specified, estimation commands will not build or post the coefficient table matrix $r$ (table).

If your program calls an estimation command and needs $r(t a b l e)$ to exist to perform properly, then your program will need to call

```
set coeftabresults on
```

before calling other estimation commands.

Bradley Efron (1938- ) was born in 1938 in Minnesota and studied mathematics and statistics at Caltech and Stanford; he has lived in northern California since 1960. He has worked on empirical Bayes, survival analysis, exponential families, bootstrap and jackknife methods, and confidence intervals, in conjunction with applied work in biostatistics, astronomy, and physics.

Efron is a member of the US National Academy of Sciences and was awarded the US National Medal of Science in 2005. He is by any standards one of the world's leading statisticians: his work ranges from deep and elegant contributions in theoretical statistics to pathbreaking involvement in a variety of practical applications.

## Stored results

bootstrap stores the following in e():
Scalars

When exp_list is _b, bootstrap will also carry forward most of the results already in e() from command.
In addition to the above, the following is stored in r() :

Matrices $r$ (table)
matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

Let $\widehat{\theta}$ be the observed value of the statistic, that is, the value of the statistic calculated with the original dataset. Let $i=1,2, \ldots, k$ denote the bootstrap samples, and let $\widehat{\theta}_{i}$ be the value of the statistic from the $i$ th bootstrap sample.

When the mse option is specified, the standard error is estimated as

$$
\widehat{\mathrm{se}}_{\mathrm{MSE}}=\left\{\frac{1}{k} \sum_{i=1}^{k}\left(\widehat{\theta}_{i}-\widehat{\theta}\right)^{2}\right\}^{1 / 2}
$$

Otherwise, the standard error is estimated as

$$
\widehat{\mathrm{se}}=\left\{\frac{1}{k-1} \sum_{i=1}^{k}\left(\widehat{\theta}_{i}-\bar{\theta}\right)^{2}\right\}^{1 / 2}
$$

where

$$
\bar{\theta}=\frac{1}{k} \sum_{i=1}^{k} \widehat{\theta}_{i}
$$

The variance-covariance matrix is similarly computed. The bias is estimated as

$$
\widehat{\mathrm{bias}}=\bar{\theta}-\widehat{\theta}
$$

Confidence intervals with nominal coverage rates $1-\alpha$ are calculated according to the following formulas. The normal-approximation method yields the confidence intervals

$$
\left[\widehat{\theta}-z_{1-\alpha / 2} \widehat{\mathrm{se}}, \widehat{\theta}+z_{1-\alpha / 2} \widehat{\mathrm{se}}\right]
$$

where $z_{1-\alpha / 2}$ is the $(1-\alpha / 2)$ th quantile of the standard normal distribution. If the mse option is specified, bootstrap will report the normal confidence interval using $\widehat{\operatorname{se}}_{\text {MSE }}$ instead of $\widehat{\text { sed }}$. estat bootstrap only uses $\widehat{\text { se }}$ in the normal confidence interval.

The percentile method yields the confidence intervals

$$
\left[\theta_{\alpha / 2}^{*}, \theta_{1-\alpha / 2}^{*}\right]
$$

where $\theta_{p}^{*}$ is the $p$ th quantile (the $100 p$ th percentile) of the bootstrap distribution $\left(\widehat{\theta}_{1}, \ldots, \widehat{\theta}_{k}\right)$.

Let

$$
z_{0}=\Phi^{-1}\left\{\#\left(\widehat{\theta}_{i} \leq \widehat{\theta}\right) / k\right\}
$$

where $\#\left(\widehat{\theta}_{i} \leq \widehat{\theta}\right)$ is the number of elements of the bootstrap distribution that are less than or equal to the observed statistic and $\Phi$ is the standard cumulative normal. $z_{0}$ is known as the median bias of $\widehat{\theta}$. When the ties option is specified, $z_{0}$ is estimated as $\#\left(\widehat{\theta}_{i}<\widehat{\theta}\right)+\#\left(\widehat{\theta}_{i}=\widehat{\theta}\right) / 2$, which is the number of elements of the bootstrap distribution that are less than the observed statistic plus half the number of elements that are equal to the observed statistic.

Let

$$
a=\frac{\sum_{i=1}^{n}\left(\bar{\theta}_{(\cdot)}-\widehat{\theta}_{(i)}\right)^{3}}{6\left\{\sum_{i=1}^{n}\left(\bar{\theta}_{(\cdot)}-\widehat{\theta}_{(i)}\right)^{2}\right\}^{3 / 2}}
$$

where $\widehat{\theta}_{(i)}$ are the leave-one-out (jackknife) estimates of $\widehat{\theta}$ and $\bar{\theta}_{(\cdot)}$ is their mean. This expression is known as the jackknife estimate of acceleration for $\widehat{\theta}$. Let

$$
\begin{aligned}
& p_{1}=\Phi\left\{z_{0}+\frac{z_{0}-z_{1-\alpha / 2}}{1-a\left(z_{0}-z_{1-\alpha / 2}\right)}\right\} \\
& p_{2}=\Phi\left\{z_{0}+\frac{z_{0}+z_{1-\alpha / 2}}{1-a\left(z_{0}+z_{1-\alpha / 2}\right)}\right\}
\end{aligned}
$$

where $z_{1-\alpha / 2}$ is the $(1-\alpha / 2)$ th quantile of the normal distribution. The bias-corrected and accelerated $\left(\mathrm{BC}_{a}\right)$ method yields confidence intervals

$$
\left[\theta_{p_{1}}^{*}, \theta_{p_{2}}^{*}\right]
$$

where $\theta_{p}^{*}$ is the $p$ th quantile of the bootstrap distribution as defined previously. The bias-corrected (but not accelerated) method is a special case of $\mathrm{BC}_{a}$ with $a=0$.

## Title

bootstrap postestimation - Postestimation tools for bootstrap

| Postestimation commands | predict | margins |
| :--- | :--- | :--- |
| estat | Remarks and examples | Also see |

## Postestimation commands

The following postestimation command is of special interest after bootstrap:
Command Description
estat bootstrap percentile-based and bias-corrected CI tables

The following standard postestimation commands are also available:

| Command | Description |
| :--- | :--- |
| contrast | contrasts and ANOVA-style joint tests of estimates <br> estat ic |
| Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian in- <br> formation criteria (AIC, CAIC, AICc, and BIC) |  |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) <br> cataloging estimation results |
| estimates | table of estimation results |
| etable | Hausman's specification test |
| hausman | point estimates, standard errors, testing, and inference for linear combinations of |
| lincom | coefficients |
| marginal means, predictive margins, marginal effects, and average marginal effects |  |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) <br> point estimates, standard errors, testing, and inference for nonlinear combinations <br> of coefficients |
| nlcom | predictions, residuals, influence statistics, and other diagnostic measures <br> point estimates, standard errors, testing, and inference for generalized predictions |
| predict | pairwise comparisons of estimates |
| predictnl | Wald tests of simple and composite linear hypotheses |
| pwcompare | Wald tests of nonlinear hypotheses |

The postestimation command is allowed if it may be used after command.

## predict

The syntax of predict (and even if predict is allowed) following bootstrap depends upon the command used with bootstrap. If predict is not allowed, neither is predictnl.

## margins

The syntax of margins (and even if margins is allowed) following bootstrap depends upon the command used with bootstrap.

## estat

## Description for estat

estat bootstrap displays a table of confidence intervals for each statistic from a bootstrap analysis.

## Menu for estat

Statistics $>$ Postestimation

## Syntax for estat

estat bootstrap [, options]
options
Description
bc
bca
normal
percentile
all
noheader
nolegend
verbose
normal-based CIs
percentile CIs
all available CIs
bias-corrected CIs; the default
bias-corrected and accelerated ( $\mathrm{BC}_{a}$ ) CIs
suppress table header
suppress table legend
display the full table legend
bc , bca, normal, and percentile may be used together.

## Options for estat

bc is the default and displays bias-corrected confidence intervals.
bca displays bias-corrected and accelerated confidence intervals. This option assumes that you also specified the bca option on the bootstrap prefix command.
normal displays normal approximation confidence intervals.
percentile displays percentile confidence intervals.
all displays all available confidence intervals.
noheader suppresses display of the table header. This option implies nolegend.
nolegend suppresses display of the table legend, which identifies the rows of the table with the expressions they represent.
verbose requests that the full table legend be displayed.

## Remarks and examples

> Example 1
The estat bootstrap postestimation command produces a table containing the observed value of the statistic, an estimate of its bias, the bootstrap standard error, and up to four different confidence intervals.

If we were interested merely in getting bootstrap standard errors for the model coefficients, we could use the bootstrap prefix with our estimation command. If we were interested in performing a thorough bootstrap analysis of the model coefficients, we could use the estat bootstrap postestimation command after fitting the model with the bootstrap prefix.

Using example 1 from $[\mathrm{R}]$ bootstrap, we need many more replications for the confidence interval types other than the normal based, so let's rerun the estimation command. We will reset the randomnumber seed-in case we wish to reproduce the results-increase the number of replications, and save the bootstrap distribution as a dataset called bsauto.dta.

| ```(1978 automobile data) set seed 1 bootstrap _b, reps(1000) (output omitted) . estat bootstrap, all Linear regression``` |  | saving(bsauto) bca: regress mpg wei <br> Number of obs Replications |  |  | t gear foreign$\begin{array}{lr} = & 74 \\ = & 1000 \end{array}$ |  |

|  |  |  |  | 24.99072 | 46.40419 | (BCa) |

Key: N: Normal
P: Percentile
BC: Bias-corrected
$\mathrm{BCa}:$ Bias-corrected and accelerated
The estimated standard errors here differ from our previous estimates using only 100 replications by, respectively, $7 \%, 6 \%, 8 \%$, and $4 \%$; see example 1 of [R] bootstrap. So much for our advice that $50-200$ replications are good enough to estimate standard errors. Well, the more replications the better-that advice you should believe.

Which of the methods to compute confidence intervals should we use? If the statistic is unbiased, the percentile ( P ) and bias-corrected ( BC ) methods should give similar results. The bias-corrected confidence interval will be the same as the percentile confidence interval when the observed value of the statistic is equal to the median of the bootstrap distribution. Thus, for unbiased statistics, the two methods should give similar results as the number of replications becomes large. For biased statistics, the bias-corrected method should yield confidence intervals with better coverage probability (closer to the nominal value of $95 \%$ or whatever was specified) than the percentile method. For statistics with variances that vary as a function of the parameter of interest, the bias-corrected and accelerated method $\left(\mathrm{BC}_{a}\right)$ will typically have better coverage probability than the others.

When the bootstrap distribution is approximately normal, all of these methods should give similar confidence intervals as the number of replications becomes large. If we examine the normality of these bootstrap distributions using, say, the pnorm command (see [R] Diagnostic plots), we see that they closely follow a normal distribution. In this case, the normal approximation would also be a valid choice. The chief advantage of the normal-approximation method is that it (supposedly) requires fewer replications than the other methods. Of course, it should be used only when the bootstrap distribution exhibits normality.

We can load bsauto.dta containing the bootstrap distributions for these coefficients:

We can now run other commands, such as pnorm, on the bootstrap distributions. As with all standard estimation commands, we can use the bootstrap command to replay its output table. The default variable names assigned to the statistics in exp_list are _bs_1, _bs_2, ..., and each variable is labeled with the associated expression. The naming convention for the extended expressions _b and _se is to prepend _ $\mathrm{b}_{-}$and _se_, respectively, onto the name of each element of the coefficient vector. Here the first coefficient is _b [weight], so bootstrap named it _b_weight.

## Title

boxcox - Box-Cox regression models

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

boxcox finds the maximum likelihood estimates of the parameters of the Box-Cox transform, the coefficients on the independent variables, and the standard deviation of the normally distributed errors. Any depvar or indepvars to be transformed must be strictly positive. Options can be used to control which variables remain untransformed.

## Quick start

Box-Cox transform of y in a model of y as a function of x 1
boxcox y x1
Same as above
boxcox y x1, model(lhsonly)
Likelihood-ratio test for each scale-variant parameter
boxcox y x1, lrtest
Different transform for each side and adding covariates x 2 and x 3
boxcox y x1 x2 x3, model(theta)
Same transform for both sides, and include x 3 as an untransformed variable transformation
boxcox y x1 x2, model(lambda) notrans(x3)

## Menu

Statistics $>$ Linear models and related $>$ Box-Cox regression

## Syntax

## boxcox depvar [indepvars] [if] [in] [weight] [, options]

options

nologlr
maximize_options
suppress constant term
left-hand-side Box-Cox model; the default
right-hand-side Box-Cox model
both sides Box-Cox model with same parameter both sides Box-Cox model with different parameters do not transform specified independent variables
depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bootstrap, by, collect, jackknife, rolling, statsby, and xi are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see $[\mathrm{R}]$ bootstrap.
fweights and iweights are allowed; see [U] 11.1.6 weight.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

noconstant; see [R] Estimation options.
model (lhsonly $\mid$ rhsonly $\mid$ lambda $\mid$ theta) specifies which of the four models to fit.
model(lhsonly) applies the Box-Cox transform to depvar only. model (lhsonly) is the default. model (rhsonly) applies the transform to the indepvars only.
model (lambda) applies the transform to both depvar and indepvars, and they are transformed by the same parameter.
model(theta) applies the transform to both depvar and indepvars, but this time, each side is transformed by a separate parameter.
notrans (varlist) specifies that the variables in varlist not be transformed when included in the model. You can specify notrans (varlist) with model (lhsonly), but the results will be the same as specifying the variables in varlist in indepvars.
lrtest specifies that a likelihood-ratio test of significance be performed and reported for each independent variable.
$\qquad$ Maximization
$\log$ and nolog specify whether to display the iteration log. The iteration $\log$ is displayed by default unless you used set iterlog off to suppress it; see set iterlog in [R] set iter. These options control the iteration log produced by the full model and, if option lrtest is specified, by the fitted restricted models.
nologlr suppresses the iteration $\log$ when fitting the restricted models required by the lrtest option. maximize_options: iterate(\#) and from(init_specs); see [R] Maximize.

## Remarks and examples

Remarks are presented under the following headings:

Introduction<br>Theta model<br>Lambda model<br>Left-hand-side-only model<br>Right-hand-side-only model

## Introduction

The Box-Cox transform

$$
y^{(\lambda)}=\frac{y^{\lambda}-1}{\lambda}
$$

has been widely used in applied data analysis. Box and Cox (1964) developed the transformation and argued that the transformation could make the residuals more closely normal and less heteroskedastic. Cook and Weisberg (1982) discuss the transform in this light. Because the transform embeds several popular functional forms, it has received some attention as a method for testing functional forms, in particular,

$$
y^{(\lambda)}= \begin{cases}y-1 & \text { if } \lambda=1 \\ \ln (y) & \text { if } \lambda=0 \\ 1-1 / y & \text { if } \lambda=-1\end{cases}
$$

Davidson and MacKinnon (1993) discuss this use of the transform. Atkinson (1985) also gives a good general treatment.

## Theta model

boxcox obtains the maximum likelihood estimates of the parameters for four different models. The most general of the models, the theta model, is

$$
y_{j}^{(\theta)}=\beta_{0}+\beta_{1} x_{1 j}^{(\lambda)}+\beta_{2} x_{2 j}^{(\lambda)}+\cdots+\beta_{k} x_{k j}^{(\lambda)}+\gamma_{1} z_{1 j}+\gamma_{2} z_{2 j}+\cdots+\gamma_{l} z_{l j}+\epsilon_{j}
$$

where $\epsilon \sim N\left(0, \sigma^{2}\right)$. Here the dependent variable, $y$, is subject to a Box-Cox transform with parameter $\theta$. Each of the indepvars, $x_{1}, x_{2}, \ldots, x_{k}$, is transformed by a Box-Cox transform with parameter $\lambda$. The $z_{1}, z_{2}, \ldots, z_{l}$ specified in the notrans() option are independent variables that are not transformed.

Box and Cox (1964) argued that this transformation would leave behind residuals that more closely follow a normal distribution than those produced by a simple linear regression model. Bear in mind that the normality of $\epsilon$ is assumed and that boxcox obtains maximum likelihood estimates of the $k+l+4$ parameters under this assumption. boxcox does not choose $\lambda$ and $\theta$ so that the residuals are approximately normally distributed. If you are interested in this type of transformation to normality, see the official Stata commands lnskew0 and bcskew0 in [R] Inskew0. However, those commands work on a more restrictive model in which none of the independent variables is transformed.

## > Example 1

Below, we fit a theta model to a nonrepresentative extract of the Second National Health and Nutrition Examination Survey (NHANES II) dataset discussed in McDowell et al. (1981).

We model individual-level diastolic blood pressure (bpdiast) as a function of the transformed variables body mass index (bmi) and cholesterol level (tcresult) and of the untransformed variables age (age) and sex (sex).
. use https://www.stata-press.com/data/r18/nhanes2
. boxcox bpdiast bmi tcresult, notrans(age sex) model(theta) lrtest
Fitting comparison model
$\begin{array}{ll}\text { Iteration 0: } & \text { Log likelihood }=-41178.61 \\ \text { Iteration 1: } & \text { Log likelihood }=-41032.51 \\ \text { Iteration 2: } & \text { Log likelihood }=-41032.488 \\ \text { Iteration 3: } & \text { Log likelihood }=-41032.488\end{array}$
Fitting full model

| theta=lambda $=-1$ | -40162.898 | 775.82 | 0.000 |
| theta=lambda $=$ | 0 | -39790.945 | 31.92 |
| theta=lambda $=$ | 1 | -39928.606 | 307.24 |

The output is composed of the iteration logs and three distinct tables. The first table contains a standard header for a maximum likelihood estimator and a standard output table for the BoxCox transform parameters. The second table contains the estimates of the scale-variant parameters. The third table contains the output from likelihood-ratio tests on three standard functional form specifications.

The right-hand-side and the left-hand-side transformations each add to the regression fit at the $1 \%$ significance level and are both positive but less than 1 . All the variables have significant impacts on diastolic blood pressure, bpdiast. As expected, the transformed variables-the body mass index, bmi, and cholesterol level, tcresult-contribute to higher blood pressure. The last output table shows that the linear, multiplicative inverse, and $\log$ specifications are strongly rejected.

## - Technical note

Spitzer (1984) showed that the Wald tests of the joint significance of the coefficients of the right-hand-side variables, either transformed or untransformed, are not invariant to changes in the scale of the transformed dependent variable. Davidson and MacKinnon (1993) also discuss this point. This problem demonstrates that Wald statistics can be manipulated in nonlinear models. Lafontaine and White (1986) analyze this problem numerically, and Phillips and Park (1988) analyze it by using Edgeworth expansions. See Drukker (2000) for a more detailed discussion of this issue. Because the parameter estimates and their Wald tests are not scale invariant, no Wald tests or confidence intervals are reported for these parameters. However, when the lrtest option is specified, likelihood-ratio tests are performed and reported. Schlesselman (1971) showed that, if a constant is included in the model, the parameter estimates of the Box-Cox transforms are scale invariant. For this reason, we strongly recommend that you not use the noconstant option.

The lrtest option does not perform a likelihood-ratio test on the constant, so no value for this statistic is reported. Unless the data are properly scaled, the restricted model does not often converge. For this reason, no likelihood-ratio test on the constant is performed by the lrtest option. However, if you have a special interest in performing this test, you can do so by fitting the constrained model separately. If problems with convergence are encountered, rescaling the data by their means may help.

## Lambda model

A less general model than the one above is called the lambda model. It specifies that the same parameter be used in both the left-hand-side and right-hand-side transformations. Specifically,

$$
y_{j}^{(\lambda)}=\beta_{0}+\beta_{1} x_{1 j}^{(\lambda)}+\beta_{2} x_{2 j}^{(\lambda)}+\cdots+\beta_{k} x_{k j}^{(\lambda)}+\gamma_{1} z_{1 j}+\gamma_{2} z_{2 j}+\cdots+\gamma_{l} z_{l j}+\epsilon_{j}
$$

where $\epsilon \sim N\left(0, \sigma^{2}\right)$. Here the depvar variable, $y$, and each of the indepvars, $x_{1}, x_{2}, \ldots, x_{k}$, is transformed by a Box-Cox transform with the common parameter $\lambda$. Again, the $z_{1}, z_{2}, \ldots, z_{l}$ are independent variables that are not transformed.

## Left-hand-side-only model

Even more restrictive than a common transformation parameter is transforming the dependent variable only. Because the dependent variable is on the left-hand side of the equation, this model is known as the lhsonly model. Here you are estimating the parameters of the model

$$
y_{j}^{(\theta)}=\beta_{0}+\beta_{1} x_{1 j}+\beta_{2} x_{2 j}+\cdots+\beta_{k} x_{k j}+\epsilon_{j}
$$

where $\epsilon \sim N\left(0, \sigma^{2}\right)$. Here only the depvar, $y$, is transformed by a Box-Cox transform with the parameter $\theta$.

## > Example 2

In this example, we model the transform of diastolic blood pressure as a linear combination of the untransformed body mass index, cholesterol level, age, and sex.

| . boxcox bpdiast bmi tcresult age sex, model <br> Fitting comparison model <br> Fitting full model <br> Fitting comparison models for LR tests |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |
| Number of ob LR chi2(4) |  |  |  |  |  |  |
| Log likelihood $=-39777.709$ Prob > chi2 |  |  |  |  |  |  |
| bpdiast | Coefficient | Std. err | . $\quad \mathrm{z}$ | $\mathrm{P}>\|z\|$ |  | [95\% |
| /theta | . 2073268 | . 0452895 | 4.58 | 0.000 |  | . 118 |
| Estimates of scale-variant parameters |  |  |  |  |  |  |
|  | Coefficient chi2(df) P>chi2(df) df of chi2 |  |  |  |  |  |
| Notrans |  |  |  |  |  |  |
| bmi | $\begin{array}{lll}.0272628 & 1375.841 & 0.000\end{array}$ |  |  |  |  |  |
| tcresult | . $0006929 \quad 82.380 \quad 0.000$ |  |  |  |  |  |
| age | . $0040141 \quad 334.117 \quad 0.000$ |  |  |  |  |  |
| sex | $\begin{array}{llll}-.1122274 & 263.219 & 0.000 & 1\end{array}$ |  |  |  |  |  |
| _cons | 6.302855 |  |  |  |  |  |
| /sigma | . 3476615 |  |  |  |  |  |
| Test HO : | Restricted log likelihood | LR statistic |  | Prob > chi2 |  |  |
|  |  |  | hi2 Pro |  |  |  |
| $\begin{aligned} \text { theta } & =-1 \\ \text { theta } & =0 \\ \text { theta } & =1 \end{aligned}$ | $\begin{aligned} & -40146.678 \\ & -39788.241 \\ & -39928.606 \end{aligned}$ | 737.94 |  | 0.000 |  |  |
|  |  | 21.06 |  | 0.000 |  |  |
|  |  | 301.79 |  | 0.000 |  |  |

The maximum likelihood estimate of the transformation parameter for this model is positive and significant. Once again, all the scale-variant parameters are significant, and we find a positive impact of body mass index (bmi) and cholesterol levels (tcresult) on the transformed diastolic blood pressure (bpdiast). This model rejects the linear, multiplicative inverse, and log specifications.

## Right-hand-side-only model

The fourth model leaves the depvar alone and transforms a subset of the indepvars using the parameter $\lambda$. This is the rhsonly model. In this model, the depvar, $y$, is given by

$$
y_{j}=\beta_{0}+\beta_{1} x_{1 j}^{(\lambda)}+\beta_{2} x_{2 j}^{(\lambda)}+\cdots+\beta_{k} x_{k j}^{(\lambda)}+\gamma_{1} z_{1 j}+\gamma_{2} z_{2 j}+\cdots+\gamma_{l} z_{l j}+\epsilon_{j}
$$

where $\epsilon \sim N\left(0, \sigma^{2}\right)$. Here each of the indepvars, $x_{1}, x_{2}, \ldots, x_{k}$, is transformed by a Box-Cox transform with the parameter $\lambda$. Again, the $z_{1}, z_{2}, \ldots, z_{l}$ are independent variables that are not transformed.

## > Example 3

Now, we consider a rhsonly model in which the regressors sex and age are not transformed.

Estimates of scale-variant parameters

|  | Coefficient chi2(df) |  | $\mathrm{P}>\mathrm{chi2}(\mathrm{df})$ | df of chi2 |
| :---: | :---: | :---: | :---: | :---: |
| Notrans |  |  |  |  |
| sex | -3.544042 | 235.020 | 0.000 | 1 |
| age | . 128809 | 311.754 | 0.000 | 1 |
| _cons | 50.01498 |  |  |  |
| Trans |  |  |  |  |
| bmi | 1.418215 | 1396.709 | 0.000 | 1 |
| tcresult | . 0462964 | 78.500 | 0.000 | 1 |
| /sigma | 11.4557 |  |  |  |

| Test <br> H0: | Restricted <br> log likelihood | LR statistic <br> chi2 | Prob > chi2 |
| :---: | :---: | :---: | :---: |
| lambda $=-1$ | -39989.331 | 122.24 | 0.000 |
| lambda $=$ | 0 | -39942.945 | 29.47 |
| lambda $=$ | 1 | -39928.606 | 0.79 |

The maximum likelihood estimate of the transformation parameter in this model is positive and significant at the $1 \%$ level. The transformed bmi coefficient behaves as expected, and the remaining scale-variant parameters are significant at the $1 \%$ level. This model rejects the multiplicative inverse and $\log$ specifications strongly. However, we cannot reject the hypothesis that the model is linear.

## Stored results

boxcox stores the following in e() :
Scalars
$e(N) \quad$ number of observations
e(11) $\quad \log$ likelihood
$e$ (chi2) LR statistic of full vs. comparison
$e\left(\mathrm{df} \_\mathrm{m}\right) \quad$ full model degrees of freedom
$\mathrm{e}(110) \quad \log$ likelihood of the restricted model
$e\left(d f \_r\right) \quad$ restricted model degrees of freedom
e(ll_t1) $\quad$ log likelihood of model $\lambda=\theta=1$
$e($ chi2_t1) LR of $\lambda=\theta=1$ vs. full model
e (p_t1) $\quad p$-value of $\lambda=\theta=1$ vs. full model
$\mathrm{e}\left(11 \_\right.$tm1) $\quad \log$ likelihood of model $\lambda=\theta=-1$
$e($ chi2_tm1) LR of $\lambda=\theta=-1$ vs. full model
$\mathrm{e}($ p_tm1) $\quad p$-value of $\lambda=\theta=-1$ vs. full model
e(ll_t0) $\quad$ log likelihood of model $\lambda=\theta=0$
e(chi2_t0) LR of $\lambda=\theta=0$ vs. full model
e (p_t0) $\quad p$-value of $\lambda=\theta=0$ vs. full model
$e$ (rank) rank of e(V)
$e(i c) \quad$ number of iterations
$e(r c)$ return code
Macros
$e(\mathrm{cmd})$
boxcox
e(cmdline) command as typed
e(depvar) name of dependent variable
e(model) lhsonly, rhsonly, lambda, or theta
$e$ (wtype) weight type
e(wexp)
$e$ (ntrans)
e(chi2type)
weight expression
yes if untransformed indepvars
$e$ (lrtest) lrtest, if requested
e(properties)
b V
e(predict)
e(marginsnotok)
program used to implement predict
predictions disallowed by margins
Matrices
e(b)
e(V)
$\mathrm{e}(\mathrm{pm}) \quad p$-values for LR tests on indepvars
$e(d f) \quad$ degrees of freedom of LR tests on indepvars
e(chi2m)
coefficient vector
variance-covariance matrix of the estimators (see note below)

LR statistics for tests on indepvars
Functions
e(sample) marks estimation sample
$e(V)$ contains all zeros, except for the elements that correspond to the parameters of the Box-Cox transform.

## Methods and formulas

In the internal computations,

$$
y^{(\lambda)}= \begin{cases}\frac{y^{\lambda}-1}{\lambda} & \text { if }|\lambda|>10^{-10} \\ \ln (y) & \text { otherwise }\end{cases}
$$

The unconcentrated log likelihood for the theta model is

$$
\ln L=\left(\frac{-N}{2}\right)\left\{\ln (2 \pi)+\ln \left(\sigma^{2}\right)\right\}+(\theta-1) \sum_{i=1}^{N} \ln \left(y_{i}\right)-\left(\frac{1}{2 \sigma^{2}}\right) \mathrm{SSR}
$$

where

$$
\operatorname{SSR}=\sum_{i=1}^{N}\left(y_{i}^{(\theta)}-\beta_{0}+\beta_{1} x_{i 1}^{(\lambda)}+\beta_{2} x_{i 2}^{(\lambda)}+\cdots+\beta_{k} x_{i k}^{(\lambda)}+\gamma_{1} z_{i 1}+\gamma_{2} z_{i 2}+\cdots+\gamma_{l} z_{i l}\right)^{2}
$$

Writing the SSR in matrix form,

$$
\operatorname{SSR}=\left(\mathbf{y}^{(\theta)}-\mathbf{X}^{(\lambda)} \mathbf{b}^{\prime}-\mathbf{Z g}^{\prime}\right)^{\prime}\left(\mathbf{y}^{(\theta)}-\mathbf{X}^{(\lambda)} \mathbf{b}^{\prime}-\mathbf{Z g}^{\prime}\right)
$$

where $\mathbf{y}^{(\theta)}$ is an $N \times 1$ vector of elementwise transformed data, $\mathbf{X}^{(\lambda)}$ is an $N \times k$ matrix of elementwise transformed data, $\mathbf{Z}$ is an $N \times l$ matrix of untransformed data, $\mathbf{b}$ is a $1 \times k$ vector of coefficients, and $\mathbf{g}$ is a $1 \times l$ vector of coefficients. Letting

$$
\mathbf{W}_{\lambda}=\left(\mathbf{X}^{(\lambda)} \mathbf{Z}\right)
$$

be the horizontal concatenation of $\mathbf{X}^{(\lambda)}$ and $\mathbf{Z}$ and

$$
\mathbf{d}^{\prime}=\binom{\mathbf{b}^{\prime}}{\mathbf{g}^{\prime}}
$$

be the vertical concatenation of the coefficients yields

$$
\operatorname{SSR}=\left(\mathbf{y}^{(\theta)}-\mathbf{W}_{\lambda} \mathbf{d}^{\prime}\right)^{\prime}\left(\mathbf{y}^{(\theta)}-\mathbf{W}_{\lambda} \mathbf{d}^{\prime}\right)
$$

For given values of $\lambda$ and $\theta$, the solutions for $\mathbf{d}^{\prime}$ and $\sigma^{2}$ are

$$
\widehat{\mathbf{d}}^{\prime}=\left(W_{\lambda}^{\prime} W_{\lambda}\right)^{-1} W_{\lambda}^{\prime} y^{(\theta)}
$$

and

$$
\widehat{\sigma}^{2}=\frac{1}{N}\left(\mathbf{y}^{(\theta)}-W_{\lambda} \widehat{d}^{\prime}\right)^{\prime}\left(y^{(\theta)}-W_{\lambda}{\widehat{d^{\prime}}}^{\prime}\right)
$$

Substituting these solutions into the log-likelihood function yields the concentrated log-likelihood function

$$
\ln L_{c}=\left(-\frac{N}{2}\right)\left\{\ln (2 \pi)+1+\ln \left(\widehat{\sigma}^{2}\right)\right\}+(\theta-1) \sum_{i=1}^{N} \ln \left(y_{i}\right)
$$

Similar calculations yield the concentrated log-likelihood function for the lambda model,

$$
\ln L_{c}=\left(-\frac{N}{2}\right)\left\{\ln (2 \pi)+1+\ln \left(\widehat{\sigma}^{2}\right)\right\}+(\lambda-1) \sum_{i=1}^{N} \ln \left(y_{i}\right)
$$

the lhsonly model,

$$
\ln L_{c}=\left(-\frac{N}{2}\right)\left\{\ln (2 \pi)+1+\ln \left(\widehat{\sigma}^{2}\right)\right\}+(\theta-1) \sum_{i=1}^{N} \ln \left(y_{i}\right)
$$

and the rhsonly model,

$$
\ln L_{c}=\left(-\frac{N}{2}\right)\left\{\ln (2 \pi)+1+\ln \left(\widehat{\sigma}^{2}\right)\right\}
$$

where $\widehat{\sigma}^{2}$ is specific to each model and is defined analogously to that in the theta model.

## Postestimation commands

The following postestimation commands are available after boxcox:

| Command | Description |
| :---: | :---: |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| hausman | Hausman's specification test |
| *lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| * nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | predictions and residuals |
| * test | Wald tests of simple and composite linear hypotheses |
| * testnl | Wald tests of nonlinear hypotheses |

[^8]
## predict

## Description for predict

predict creates a new variable containing predictions such as predicted values and residuals.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic options]
```

statistic Description
Main
yhat predicted value of $y$; the default residuals residuals
options Description
Options
smearing compute statistic using smearing method; the default
btransform compute statistic using back-transform method

These statistics are available both in and out of sample; type predict . . . if e (sample) ... if wanted only for the estimation sample.

## Options for predict

$\qquad$ Main
yhat, the default, calculates the predicted value of the dependent variable.
residuals calculates the residuals, that is, the observed value minus the predicted value.
$\qquad$ Options
smearing calculates the statistics yhat and residuals using the smearing method proposed by Duan (1983) (see Methods and formulas for a description of this method). smearing is the default. btransform calculates the statistics yhat and residuals using the back-transform method (see Methods and formulas for a description of this method).

## Remarks and examples

Below, we present two examples that illustrate how to use the smearing and btransform options.
> Example 1: Predictions with the smearing option
In this example, we calculate the predicted values of diastolic blood pressure, bpdiast, that arise from the theta model calculated in example 1 of $[R]$ boxcox.

```
. use https://www.stata-press.com/data/r18/nhanes2
. boxcox bpdiast bmi tcresult, notrans(age sex) model(theta) lrtest
    (output omitted)
. predict yhat
(statistic yhat and option smearing are assumed)
```

In the expression above, yhat is the name we gave to the estimates of the conditional expectation. Given that we did not specify any statistic or option, the corresponding defaults yhat and smearing were assumed.

As the summary table below illustrates, the mean of the dependent variable is close to the mean of the predicted value yhat. This indicates that the theta model does a good job approximating the true value of diastolic blood pressure, bpdiast.
. summarize bpdiast yhat

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| bpdiast | 10,351 | 81.715 | 12.92722 | 35 | 150 |
| yhat | 10,351 | 81.71406 | 5.983486 | 66.93709 | 110.5283 |

Similarly, we could have asked that residuals be calculated. Here we again use the default smearing option:

```
. predict resid, residuals
(option smearing assumed to compute residuals)
```

> Example 2: Predictions with the btransform option
In this example, we illustrate the tradeoffs involved by using the btransform option as opposed to the default smearing option. Continuing with example 1, we compute the predicted values using the back-transform method.

```
. predict yhatb, btransform
(statistic yhat assumed)
```

We now compute the predicted values using the smearing option and summarize both computations.
. predict yhats
(statistic yhat and option smearing are assumed)
• summarize bpdiast yhats yhatb
Variable

As can be seen from the mean and the standard deviation of the summary table, the predicted values using the back-transform method give biased estimates but are less variable than those coming from the smearing method. However, the efficiency loss is small compared with the bias reduction.

## - Technical note

boxcox estimates variances only for the $\lambda$ and $\theta$ parameters (see the technical note in [R] boxcox), so the extent to which postestimation commands can be used following boxcox is limited. Formulas used in lincom, nlcom, test, and testnl are dependent on the estimated variances. Therefore, the use of these commands is limited and generally applicable only to inferences on the $\lambda$ and $\theta$ coefficients.

## Methods and formulas

The computation of the expected value of the dependent variable conditional on the regressors for the Box-Cox model does not follow the logic of the standard linear regression model because the random disturbance does not vanish from the conditional expectation and must be accounted for. To show this, we will revisit the lhsonly model described by

$$
y_{j}^{(\lambda)}=\beta_{0}+\beta_{1} x_{1 j}+\beta_{2} x_{2 j}+\cdots+\beta_{(k-1)} x_{(k-1) j}+\epsilon_{j}
$$

where

$$
y^{(\lambda)}=\frac{y^{\lambda}-1}{\lambda}
$$

and

$$
y^{(\lambda)}= \begin{cases}y-1 & \text { if } \lambda=1 \\ \ln (y) & \text { if } \lambda=0 \\ 1-1 / y & \text { if } \lambda=-1\end{cases}
$$

For the presentation below, let $\mathbf{y}^{(\lambda)}$ be an $N \times 1$ vector of elementwise transformed data, $\mathbf{X}$ be an $N \times k$ matrix of regressors, $\boldsymbol{\beta}$ be a $k \times 1$ vector of parameters, and $\iota$ be an $n \times 1$ vector of ones.

If we were interested in $E\left(\mathbf{y}^{(\lambda)} \mid \mathbf{X}\right)$, then the conventional logic would follow, and we would obtain predictions as $y^{(\widehat{\lambda})}=\mathbf{X} \widehat{\boldsymbol{\beta}}$, where $\widehat{\boldsymbol{\beta}}$ is the estimate of $\boldsymbol{\beta}$. However, to estimate the conditional expectation of $\mathbf{y}$, we need to isolate it on the left-hand side of the model. In the case of the lhsonly model, this yields

$$
\mathbf{y}=\{\lambda(\mathbf{X} \widehat{\boldsymbol{\beta}}+\boldsymbol{\epsilon})+\boldsymbol{\iota}\}^{1 / \lambda}
$$

The conditional expectation is then defined by

$$
E(\mathbf{y} \mid \mathbf{X})=\int\{\lambda(\mathbf{X} \boldsymbol{\beta}+\boldsymbol{\epsilon})+\boldsymbol{\iota}\}^{1 / \lambda} d F(\boldsymbol{\epsilon} \mid \mathbf{X})
$$

In the expression above, $d F(\epsilon \mid \mathbf{X})$ corresponds to the cdf of $\epsilon$ conditional on the regressors. It is also clear that the random disturbance does not vanish.

To address this issue, the default methodology used by predict computes this integral using the smearing method proposed by Duan (1983) to implement a two-step estimator, as was suggested by Abrevaya (2002).

In the first step, we get an estimate for $\boldsymbol{\epsilon}$ defined as

$$
\widehat{\boldsymbol{\epsilon}}=\mathbf{y}^{(\widehat{\lambda})}-\mathbf{X} \widehat{\boldsymbol{\beta}}
$$

In the second step, for each $j$ we compute our predicted values as the sum:

$$
\widehat{y}_{j}=\frac{1}{N} \sum_{i=1}^{N}\left\{\widehat{\lambda}\left(\mathbf{x}_{j} \widehat{\boldsymbol{\beta}}+\widehat{\epsilon}_{i}\right)+1\right\}^{1 / \widehat{\lambda}}
$$

In the expression above, $\mathbf{x}_{j}$ is the $j$ th row of the matrix $\mathbf{X}$ (in other words, the values of the covariates for individual $j$ ), and $\widehat{\epsilon}_{i}$ is the residual for individual $i$. The result of this summation gives us the conditional expectation of the dependent variable for individual $j$. Given that this operation is performed for each individual $j$, the methodology is computationally intensive.

The back-transform method can be understood as a naïve estimate that disregards the random disturbance. The predictions using this approach are given by

$$
\widehat{y}_{j}=\left(\widehat{\lambda} \mathbf{x}_{j} \widehat{\boldsymbol{\beta}}+1\right)^{1 / \widehat{\lambda}}
$$

## Title

brier - Brier score decomposition

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Option | Remarks and examples | Stored results | Methods and formulas |
| Acknowledgment | References | Also see |  |

## Description

brier computes the Yates, Sanders, and Murphy decompositions of the Brier mean probability score. The Brier score is a measure of disagreement between the observed outcome and a forecast (prediction).

## Quick start

Brier score decomposition for binary outcome y and predicted probability pvar brier y pvar

Same as above, but use 5 groups rather than 10 to compute the decomposition brier y pvar, group(5)

## Menu

Statistics $>$ Epidemiology and related $>$ Other $>$ Brier score decomposition

## Syntax

brier outcomevar forecastvar [if] [in] [, group(\#)]
outcomevar is a binary variable indicating the outcome of the experiment.
forecastvar is the corresponding probability of a positive outcome and must be between 0 and 1 .
by and collect are allowed; see [U] 11.1.10 Prefix commands.

## Option

> Main
> group(\#) specifies the number of groups that will be used to compute the decomposition. group(10) is the default.

## Remarks and examples

You have a binary ( $0 / 1$ ) response and a formula that predicts the corresponding probabilities of having observed a positive outcome (1). If the probabilities were obtained from logistic regression, there are many methods that assess goodness of fit (see, for instance, [R] estat gof). However, the probabilities might be computed from a published formula or from a model fit on another sample, both completely unrelated to the data at hand, or perhaps the forecasts are not from a formula at all. In any case, you now have a test dataset consisting of the forecast probabilities and observed outcomes. Your test dataset might, for instance, record predictions made by a meteorologist on the probability of rain along with a variable recording whether it actually rained.

The Brier score is an aggregate measure of disagreement between the observed outcome and a prediction - the average squared error difference. The Brier score decomposition is a partition of the Brier score into components that suggest reasons for discrepancy. These reasons fall roughly into three groups: 1) lack of overall calibration between the average predicted probability and the actual probability of the event in your data, 2) misfit of the data in groups defined within your sample, and 3 ) inability to match actual 0 and 1 responses.
Problem 1 refers to simply overstating or understating the probabilities.
Problem 2 refers to what is standardly called a goodness-of-fit test: the data are grouped, and the predictions for the group are compared with the outcomes.
Problem 3 refers to an individual-level measure of fit. Imagine that the grouped outcomes are predicted on average correctly but that within the group, the outcomes are poorly predicted.
Using logit or probit analysis to fit your data will guarantee that there is no lack of fit due to problem 1 , and a good model fitter will be able to avoid problem 2. Problem 3 is inherent in any prediction exercise.
> Example 1
We have data on the outcomes of 20 basketball games (win) and the probability of victory predicted by a local pundit (for).
. use https://www.stata-press.com/data/r18/bball
. summarize win for
Variable

win
for

The mean probabilities of forecast and outcome are simply the mean of the predicted probabilities and the actual outcomes (wins/losses). The correlation is the product-moment correlation between them.

The Brier score measures the total difference between the event (winning) and the forecast probability of that event as an average squared difference. As a benchmark, a perfect forecaster would have a Brier score of 0 , a perfect misforecaster (predicts probability of win is 1 when loses and 0 when wins) would have a Brier score of 1 , and a fence sitter (forecasts every game as $50 / 50$ ) would have a Brier score of 0.25 . Our pundit is doing reasonably well.

Spiegelhalter's $z$ statistic is a standard normal test statistic for testing whether an individual Brier score is extreme. The ROC area is the area under the receiver operating curve, and the associated test is a test of whether it is greater than 0.5 . The more accurate the forecast probabilities, the larger the ROC area.

The Sanders-modified Brier score measures the difference between a grouped forecast measure and the event, where the data are grouped by sorting the sample on the forecast and dividing it into approximately equally sized groups. The difference between the modified and the unmodified score is typically minimal. For this and the other statistics that require grouping-the Sanders and Murphy resolutions and reliability-in-the-small-to be well defined, group boundaries are chosen so as not to allocate observations with the same forecast probability to different groups. This task is done by grouping on the forecast using xtile, $n(\#)$, with \# being the number of groups; see [D] pctile.

The Sanders resolution measures error that arises from statistical considerations in evaluating the forecast for a group. A group with all positive or all negative outcomes would have a Sanders resolution of 0 ; it would most certainly be feasible to predict exactly what happened to each member of the group. If the group had $40 \%$ positive responses, on the other hand, a forecast that assigned $p=0.4$ to each member of the group would be a good one, and yet, there would be "errors" in
the squared difference sense. The "error" would be $(1-0.4)^{2}$ or $(0-0.4)^{2}$ for each member. The Sanders resolution is the average across groups of such "expected" errors. The 0.1400 value in our data from an overall Brier score of 0.1828 or 0.1861 suggests that a substantial portion of the "error" in our data is inherent.

Outcome index variance is just the variance of the outcome variable. This is the expected value of the Brier score if all the forecast probabilities were merely the average observed outcome. Remember that a fence sitter has an expected Brier score of 0.25 ; a smarter fence sitter (who would guess $p=0.65$ for these data) would have a Brier score of 0.2275 .

The Murphy resolution measures the variation in the average outcomes across groups. If all groups have the same frequency of positive outcomes, little information in any forecast is possible, and the Murphy resolution is 0 . If groups differ markedly, the Murphy resolution is as large as 0.25 . The 0.0875 means that there is some variation but not a lot, and 0.0875 is probably higher than in most real cases. If you had groups in your data that varied between $40 \%$ and $60 \%$ positive outcomes, the Murphy resolution would be 0.01 ; between $30 \%$ and $70 \%$, it would be 0.04 .

Reliability-in-the-small measures the error that comes from the average forecast within group not measuring the average outcome within group-a classical goodness-of-fit measure, with 0 meaning a perfect fit and 1 meaning a complete lack of fit. The calculated value of 0.0461 shows some amount of lack of fit. Remember, the number is squared, and we are saying that probabilities could be just more than $\sqrt{0.0461}=0.215$ or $21.5 \%$ off.

Forecast variance measures the amount of discrimination being attempted - that is, the variation in the forecasted probabilities. A small number indicates a fence sitter making constant predictions. If the forecasts were from a logistic regression model, forecast variance would tend to increase with the amount of information available. Our pundit shows considerable forecast variance of 0.0438 (standard deviation $\sqrt{0.0438}=0.2093$ ), which is in line with the reliability-in-the-small, suggesting that the forecaster is attempting as much variation as is available in these data.

Excess forecast variance is the amount of actual forecast variance over a theoretical minimum. The theoretical minimum - called the minimum forecast variance-corresponds to forecasts of $p_{0}$ for observations ultimately observed to be negative responses and $p_{1}$ for observations ultimately observed to be positive outcomes. Moreover, $p_{0}$ and $p_{1}$ are set to the average forecasts made for the ultimate negative and positive outcomes. These predictions would be just as good as the predictions the forecaster did make, and any variation in the actual forecast probabilities above this is useless. If this number is large, above $1 \%-2 \%$, then the forecaster may be attempting more than is possible. The 0.0285 in our data suggests this possibility.

Reliability-in-the-large measures the discrepancy between the mean forecast and the observed fraction of positive outcomes. This discrepancy will be 0 for forecasts made by most statistical models-at least when measured on the same sample used for estimation-because they, by design, reproduce sample means. For our human pundit, the 0.0294 says that there is a $\sqrt{0.0294}$, or 17 -percentage-point, difference. (This difference can also be found by calculating the difference in the averages of the observed outcomes and forecast probabilities: $0.65-0.4785=0.17$.) That difference, however, is not significant, as we would see if we typed ttest win=for; see [R] ttest. If these data were larger and the bias persisted, this difference would be a critical shortcoming of the forecast.

Twice the forecast-outcome covariance is a measure of how accurately the forecast corresponds to the outcome. The concept is similar to that of $R^{2}$ in linear regression.

## Stored results

brier stores the following in $r()$ :
Scalars

```
r(p_roc) one-sided p-value for ROC area test
r(roc_area) ROC area
r(z) Spiegelhalter's z statistic
r(p) one-sided p-value for Spiegelhalter's z test
r(brier) Brier score
r(brier_s) Sanders-modified Brier score
r(sanders) Sanders resolution
r(oiv) outcome index variance
r(murphy) Murphy resolution
r(relinsm) reliability-in-the-small
r(Var_f) forecast variance
r(Var_fex) excess forecast variance
r(Var_fmin) minimum forecast variance
r(relinla) reliability-in-the-large
r(cov_2f) 2 forecast-outcome-covariance
```

## Methods and formulas

See Wilks (2019) or Schmid and Griffith (2005) for a discussion of the Brier score.
Let $d_{j}, j=1, \ldots, N$, be the observed outcomes with $d_{j}=0$ or $d_{j}=1$, and let $f_{j}$ be the corresponding forecasted probabilities that $d_{j}$ is $1,0 \leq f_{j} \leq 1$. Assume that the data are ordered so that $f_{j+1} \geq f_{j}$ (brier sorts the data to obtain this order). Divide the data into $K$ nearly equally sized groups, with group 1 containing observations 1 through $j_{2}-1$, group 2 containing observations $j_{2}$ through $j_{3}-1$, and so on.

Define

$$
\begin{aligned}
\bar{f}_{0} & =\text { average } f_{j} \text { among } d_{j}=0 \\
\bar{f}_{1} & =\text { average } f_{j} \text { among } d_{j}=1 \\
\bar{f} & =\text { average } f_{j} \\
\bar{d} & =\text { average } d_{j} \\
\widetilde{f}_{k} & =\text { average } f_{j} \text { in group } k \\
\widetilde{d}_{k} & =\text { average } d_{j} \text { in group } k \\
\widetilde{n}_{k} & =\text { number of observations in group } k
\end{aligned}
$$

The Brier score is $\sum_{j}\left(d_{j}-f_{j}\right)^{2} / N$.
The Sanders-modified Brier score is $\sum_{j}\left(d_{j}-\widetilde{f}_{k(j)}\right)^{2} / N$.

Let $p_{j}$ denote the true but unknown probability that $d_{j}=1$. Under the null hypothesis that $p_{j}=$ $f_{j}$ for all $j$, Spiegelhalter (1986) determined that the expectation and variance of the Brier score is given by the following:

$$
\begin{aligned}
E(\text { Brier }) & =\frac{1}{N} \sum_{j=1}^{N} f_{j}\left(1-f_{j}\right) \\
\operatorname{Var}(\text { Brier }) & =\frac{1}{N^{2}} \sum_{j=1}^{N} f_{j}\left(1-f_{j}\right)\left(1-2 f_{j}\right)^{2}
\end{aligned}
$$

Denoting the observed value of the Brier score by $O$ (Brier), Spiegelhalter's $z$ statistic is given by

$$
Z=\frac{O(\text { Brier })-E(\text { Brier })}{\sqrt{\operatorname{Var}(\text { Brier })}}
$$

The corresponding $p$-value is given by the upper-tail probability of $Z$ under the standard normal distribution.

The area under the ROC curve is estimated by applying the trapezoidal rule to the empirical ROC curve. This area is Wilcoxon's test statistic, so the corresponding $p$-value is just that of a one-sided Wilcoxon test of the null hypothesis that the distribution of predictions is constant across the two outcomes.

The Sanders resolution is $\sum_{k} \widetilde{n}_{k}\left\{\widetilde{d}_{k}\left(1-\widetilde{d}_{k}\right)\right\} / N$.
The outcome index variance is $\bar{d}(1-\bar{d})$.
The Murphy resolution is $\sum_{k} \widetilde{n}_{k}\left(\widetilde{d}_{k}-\bar{d}\right)^{2} / N$.
Reliability-in-the-small is $\sum_{k} \widetilde{n}_{k}\left(\widetilde{d}_{k}-\widetilde{f}_{k}\right)^{2} / N$.
The forecast variance is $\sum_{j}\left(f_{j}-\bar{f}\right)^{2} / N$.
The minimum forecast variance is $\left\{\sum_{j \in F}\left(f_{j}-\bar{f}_{0}\right)^{2}+\sum_{j \in S}\left(f_{j}-\bar{f}_{1}\right)^{2}\right\} / N$, where $F$ is the set of observations for which $d_{j}=0$ and $S$ is the complement.

The excess forecast variance is the difference between the forecast variance and the minimum forecast variance.

Reliability-in-the-large is $(\bar{f}-\bar{d})^{2}$.
Twice the outcome covariance is $2\left(\bar{f}_{1}-\bar{f}_{0}\right) \bar{d}(1-\bar{d})$.

Glenn Wilson Brier (1913-1998) was an American meteorological statistician who, after obtaining degrees in physics and statistics, was for many years head of meteorological statistics at the US Weather Bureau in Washington, DC. In the latter part of his career, he was associated with Colorado State University. Brier worked especially on verification and evaluation of predictions and forecasts, statistical decision making, the statistical theory of turbulence, the analysis of weather modification experiments, and the application of permutation techniques.

## Acknowledgment

We thank Richard Goldstein for his contributions to this improved version of brier．

## Title

bsample - Sampling with replacement

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | References | Also see |

## Description

bsample replaces the data in memory with a bootstrap sample (random sample with replacement) drawn from the current dataset. Clusters can be optionally sampled during each replication in place of observations. Bootstrap samples can also be selected within strata.

## Quick start

Bootstrap sample with the same number of observations as the current dataset bsample

Same as above, but restrict to just 100 observations
bsample 100
Stratified bootstrap sample of 100 observations at each level of svar bsample 100, strata(svar)

Bootstrap sample of 10 clusters identified by values of cvar bsample 10, cluster(cvar)

Same as above, but create a new unique ID code for sampled clusters and store it in cvar2 bsample 10, cluster(cvar) idcluster(cvar2)

## Menu

Statistics $>$ Resampling $>$ Draw bootstrap sample

## Syntax

```
bsample [exp][if][in] [,options]
```

where $\exp$ is a standard Stata expression specifying the size of the sample; see [U] 13 Functions and expressions.
exp must be less than or equal to $\_\mathrm{N}$ (the number of observations; [U] 13.4 System variables (_variables)) when neither the cluster() nor the strata() option is specified. _N is the default when $\exp$ is not specified.

Observations that do not meet the optional if and in criteria are dropped from the resulting dataset.

options

Description
strata (varlist)
cluster (varlist)
idcluster (newvar)
weight (varname)

## Options

strata (varlist) specifies the variables identifying strata. If strata() is specified, bootstrap samples are selected within each stratum, and $\exp$ must be less than or equal to $\_\mathrm{N}$ within the defined strata.
cluster (varlist) specifies the variables identifying resampling clusters. If cluster() is specified, the sample drawn during each replication is a bootstrap sample of clusters, and exp must be less than or equal to $N_{c}$ (the number of clusters identified by the cluster() option). If strata() is also specified, exp must be less than or equal to the number of within-strata clusters.
idcluster (newvar) creates a new variable containing a unique identifier for each resampled cluster. weight (varname) specifies a variable in which the sampling frequencies will be placed. varname must be an existing variable, which will be replaced. After bsample, varname can be used as an fweight in any Stata command that accepts fweights, which can speed up resampling for commands like regress and summarize. This option cannot be combined with idcluster().
By default, bsample replaces the data in memory with the sampled observations; however, specifying the weight () option causes only the specified varname to be changed.

## Remarks and examples

Below is a series of examples illustrating how bsample is used with various sampling schemes.

## > Example 1: Bootstrap sampling

We have data on the characteristics of hospital patients and wish to draw a bootstrap sample of 200 patients. We type

```
. use https://www.stata-press.com/data/r18/bsample1
. bsample 200
. count
200
```

> Example 2: Stratified samples with equal sizes
Among the variables in our dataset is female, an indicator for the female patients. To get a bootstrap sample of 200 female patients and 200 male patients, we type

```
. use https://www.stata-press.com/data/r18/bsample1, clear
. bsample 200, strata(female)
. tabulate female
\begin{tabular}{r|rrr}
\begin{tabular}{r} 
Indicator \\
for female
\end{tabular} & Freq. & Percent & Cum. \\
\hline Male & 200 & 50.00 & 50.00 \\
Female & 200 & 50.00 & 100.00 \\
\hline Total & 400 & 100.00 &
\end{tabular}
```

## > Example 3: Stratified samples with unequal sizes

To sample 300 females and 200 males, we must generate a variable that is 300 for females and 200 for males and then use this variable in $\exp$ when we call bsample.

```
. use https://www.stata-press.com/data/r18/bsample1, clear
. generate nsamp = cond(female,300,200)
. bsample nsamp, strata(female)
. tabulate female
\begin{tabular}{r|rrr}
\begin{tabular}{r} 
Indicator \\
for female
\end{tabular} & Freq. & Percent & Cum. \\
\hline \begin{tabular}{r} 
Male
\end{tabular} & 200 & 40.00 & 40.00 \\
Female & 300 & 60.00 & 100.00 \\
\hline Total & 500 & 100.00 &
\end{tabular}
```

> Example 4: Stratified samples with proportional sizes
Our original dataset has 2,392 males and 3,418 females.
. use https://www.stata-press.com/data/r18/bsample1, clear
. tabulate female

| Indicator <br> for female | Freq. | Percent | Cum. |
| ---: | ---: | ---: | ---: |
| Male | 2,392 | 41.17 | 41.17 |
| Female | 3,418 | 58.83 | 100.00 |
| Total | 5,810 | 100.00 |  |

To sample $10 \%$ from females and males, we type

```
. bsample round(0.1*_N), strata(female)
```

bsample requires that the specified size of the sample be an integer, so we use the round () function to obtain the nearest integer to $0.1 \times 2392$ and $0.1 \times 3418$. Our sample now has 239 males and 342 females:

| . tabulate female |  |  |  |
| ---: | ---: | ---: | ---: |
| Indicator <br> for female | Freq. | Percent | Cum. |
| Male 239 41.14 41.14 <br> Female 342 58.86 100.00 <br> Total 581 100.00 . |  |  |  |

## Example 5: Samples satisfying a condition

For a bootstrap sample of 200 female patients, we type

```
. use https://www.stata-press.com/data/r18/bsample1, clear
. bsample 200 if female
. tabulate female
\begin{tabular}{r|rrr}
\begin{tabular}{r} 
Indicator \\
for female
\end{tabular} & Freq. & Percent & Cum. \\
\hline Female & 200 & 100.00 & 100.00 \\
\hline Total & 200 & 100.00 &
\end{tabular}
```

> Example 6: Generating frequency weights
To identify the sampled observations using frequency weights instead of dropping unsampled observations, we use the weight() option (we will need to supply it an existing variable name) and type

```
. use https://www.stata-press.com/data/r18/bsample1, clear
. set seed 1234
. generate fw = .
(5,810 missing values generated)
. bsample 200 if female, weight(fw)
. tabulate fw female
\begin{tabular}{r|rr|r} 
& \begin{tabular}{r} 
Indicator for female \\
Male
\end{tabular} & Female & Total \\
\hline 0 & 2,392 & 3,222 & 5,614 \\
1 & 0 & 192 & 192 \\
2 & 0 & 4 & 4 \\
\hline Total & 2,392 & 3,418 & 5,810
\end{tabular}
```

Note that $(192 \times 1)+(4 \times 2)=200$.

## > Example 7: Oversampling observations

bsample requires the expression in $\exp$ to evaluate to a number that is less than or equal to the number of observations. To sample twice as many male and female patients as there are already in memory, we must expand the data before using bsample. For example,

```
. use https://www.stata-press.com/data/r18/bsample1, clear
. set seed 1234
- expand 2
(5,810 observations created)
. bsample, strata(female)
. tabulate female
\begin{tabular}{r|rcr}
\begin{tabular}{r} 
Indicator \\
for female
\end{tabular} & Freq. & Percent & Cum. \\
\hline Male & 4,784 & 41.17 & 41.17 \\
Female & 6,836 & 58.83 & 100.00 \\
\hline Total & 11,620 & 100.00 &
\end{tabular}
```

$>$ Example 8: Stratified oversampling with unequal sizes
To sample twice as many female patients as male patients, we must expand the records for the female patients because there are less than twice as many of them as there are male patients, but first put the number of observed male patients in a local macro. After expanding the female records, we generate a variable that contains the number of observations to sample within the two groups.

```
. use https://www.stata-press.com/data/r18/bsample1, clear
. set seed 1234
. count if !female
    2,392
. local nmale = r(N)
. expand 2 if female
(3,418 observations created)
. generate nsamp = cond(female, 2*'nmale','nmale')
. bsample nsamp, strata(female)
. tabulate female
\begin{tabular}{r|rrr}
\begin{tabular}{r} 
Indicator \\
for female
\end{tabular} & Freq. & Percent & Cum. \\
\hline Male & 2,392 & 33.33 & 33.33 \\
Female & 4,784 & 66.67 & 100.00 \\
\hline Total & 7,176 & 100.00 &
\end{tabular}
```

## > Example 9: Oversampling of clusters

For clustered data, sampling more clusters than are present in the original dataset requires more than just expanding the data. To illustrate, suppose we wanted a bootstrap sample of eight clusters from a dataset consisting of five clusters of observations.

```
. use https://www.stata-press.com/data/r18/bsample2, clear
```

. tabstat $x$, stat( $n$ mean) by (group)
Summary for variables: x
Group variable: group

| group | N | Mean |
| ---: | ---: | ---: |
| A | 15 | -.3073028 |
| B | 10 | -.00984 |
| C | 11 | .0810985 |
| D | 11 | -.1989179 |
| E | 29 | -.095203 |
| Total | 76 | -.1153269 |

bsample will complain if we simply expand the dataset.

```
. use https://www.stata-press.com/data/r18/bsample2
. expand 3
(152 observations created)
. bsample 8, cluster(group)
resample size must not be greater than number of clusters
r(498);
```

Expanding the data will only partly solve the problem. We also need a new variable that uniquely identifies the copied clusters. We use the expandcl command to accomplish both these tasks; see [D] expandcl.

```
. use https://www.stata-press.com/data/r18/bsample2, clear
. set seed 1234
. expandcl 2, generate(expgroup) cluster(group)
(76 observations created)
. tabstat x, stat(n mean) by(expgroup)
Summary for variables: x
Group variable: expgroup (New cluster ID from expandcl)
\begin{tabular}{r|rr} 
expgroup & N & Mean \\
\hline 1 & \(15-.3073028\) \\
2 & 15 & -.3073028 \\
3 & 10 & -.00984 \\
4 & 10 & -.00984 \\
5 & 11 & .0810985 \\
6 & 11 & .0810985 \\
7 & \(11-.1989179\) \\
8 & 11 & -.1989179 \\
9 & 29 & -.095203 \\
10 & 29 & -.095203 \\
\hline Total & \(152-.1153269\) \\
\hline
\end{tabular}
```

. generate $\mathrm{fw}=$.
(152 missing values generated)
. bsample 8, cluster(expgroup) weight(fw)
. tabulate fw group

| fw | A | B | Croup | D | E | Total |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 15 | 10 | 22 | 11 | 58 | 116 |
| 1 | 0 | 0 | 0 | 11 | 0 | 11 |
| 2 | 15 | 0 | 0 | 0 | 0 | 15 |
| 5 | 0 | 10 | 0 | 0 | 0 | 10 |
| Total | 30 | 20 | 22 | 22 | 58 | 152 |

The results from tabulate on the generated frequency weight variable versus the original cluster ID (group) show us that the bootstrap sample contains one copy of cluster A, one copy of cluster B, two copies of cluster $C$, two copies of cluster $D$, and two copies of cluster $E(1+1+2+2+2=8)$.

## > Example 10: Stratified oversampling of clusters

Suppose that we have a dataset containing two strata with five clusters in each stratum, but the cluster identifiers are not unique between the strata. To get a stratified bootstrap sample with eight clusters in each stratum, we first use expandcl to expand the data and get a new cluster ID variable. We use cluster (strid group) in the call to expandcl; this action will uniquely identify the $2 * 5=10$ clusters across the strata.
. use https://www.stata-press.com/data/r18/bsample2, clear
. set seed 1234
. tabulate group strid

| group | strid <br> 1 | 2 | Total |
| ---: | ---: | ---: | ---: |
| A | 7 | 8 | 15 |
| B | 5 | 5 | 10 |
| C | 5 | 6 | 11 |
| D | 5 | 6 | 11 |
| E | 14 | 15 | 29 |
| Total | 36 | 40 | 76 |

. expandcl 2, generate(expgroup) cluster(strid group)
(76 observations created)
Now, we can use bsample with the expanded data, stratum ID variable, and new cluster ID variable.

```
. generate fw = .
(152 missing values generated)
```

. bsample 8, cluster(expgroup) str(strid) weight(fw)
. by strid, sort: tabulate fw group

The results from by strid: tabulate on the generated frequency weight variable versus the original cluster ID (group) show us how many times each cluster was sampled for each stratum. For stratum 1 , the bootstrap sample contains two copies of cluster A, one copy of cluster B, two copies of cluster C, one copy of cluster $D$, and two copies of cluster $E(2+1+2+1+2=8)$. For stratum 2 , the bootstrap sample contains one copy of cluster A, zero copies of cluster B, three copies of cluster C, one copy of cluster $D$, and three copies of cluster $E(1+0+3+1+3=8)$.

## Title

bstat — Report bootstrap results

| Description | Menu | Syntax | Options |
| :--- | :--- | :--- | :--- |
| Remarks and examples | Stored results | References | Also see |

## Description

bstat is a programmer's command that computes and displays estimation results from bootstrap statistics. For each variable in varlist, bstat computes a covariance matrix, estimates bias, and constructs normal confidence intervals (CIs), percentile CIs, bias-corrected (BC) CIs, and bias-corrected and accelerated $\left(\mathrm{BC}_{a}\right)$ CIs using a bootstrap dataset in memory or on disk. The computed CIs can be displayed using estat bootstrap; see [R] bootstrap postestimation.
bstat without varlist replays results from the last bootstrap estimation when results are stored in e().

## Menu

Statistics $>$ Resampling $>$ Report bootstrap results

## Syntax

Bootstrap statistics from variables
bstat [varlist] [if] [in] [, options]
Bootstrap statistics from file
bstat [namelist][using filename] [if] [in] [, options]
options Description
Main

* stat (vector) observed values for each statistic
* accel (vector) acceleration values for each statistic
*ties adjust $\mathrm{BC} / \mathrm{BCa}$ confidence intervals for ties
*mse use MSE formula for variance estimation
Reporting
level(\#)
n (\#) \# of observations from which bootstrap samples were taken
notable suppress table of results
noheader suppress table header
nolegend suppress table legend
verbose display the full table legend
title (text) use text as title for bootstrap results
display_options
control column formats and line width
*Starred options and qualifiers using, if, and in require a bootstrap dataset.
collect is allowed; see [U] 11.1.10 Prefix commands.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

stat (vector) specifies the observed value of each statistic (that is, the value of the statistic using the original dataset).
accel (vector) specifies the acceleration of each statistic, which is used to construct $\mathrm{BC}_{a}$ CIs.
ties specifies that bstat adjust for ties in the replicate values when computing the median bias used to construct BC and BCa CIs.
mse specifies that bstat compute the variance by using deviations of the replicates from the observed value of the statistics. By default, bstat computes the variance by using deviations from the average of the replicates.
$\qquad$ Reporting
level (\#); see [R] Estimation options.
$\mathrm{n}(\#)$ specifies the number of observations from which bootstrap samples were taken. This value is used in no calculations but improves the table header when this information is not saved in the bootstrap dataset.
notable suppresses the display of the output table.
noheader suppresses the display of the table header. This option implies nolegend. nolegend suppresses the display of the table legend.
verbose specifies that the full table legend be displayed. By default, coefficients and standard errors are not displayed.
title (text) specifies a title to be displayed above the table of bootstrap results; the default title is Bootstrap results.
display_options: cformat (\%fmt), pformat (\%fmt), sformat (\%fmt), and nolstretch; see [R] Estimation options.

## Remarks and examples

Remarks are presented under the following headings:
Bootstrap datasets
Creating a bootstrap dataset

## Bootstrap datasets

Although bstat allows you to specify the observed value and acceleration of each bootstrap statistic via the stat() and accel() options, programmers may be interested in what bstat uses when these options are not supplied.

When working from a bootstrap dataset, bstat first checks the data characteristics (see $[\mathrm{P}]$ char) that it understands:
_dta[bs_version] identifies the version of the bootstrap dataset. This characteristic may be empty (not defined), 2, or 3; otherwise, bstat will quit and display an error message. This version tells bstat which other characteristics to look for in the bootstrap dataset.
bstat uses the following characteristics from version 3 bootstrap datasets:

```
_dta[N]
_dta[N_strata]
_dta[N_cluster]
_dta[command]
varname[observed]
varname[acceleration]
varname[expression]
```

bstat uses the following characteristics from version 2 bootstrap datasets:
_dta [N]
_dta[N_strata]
_dta[N_cluster]
varname[observed]
varname[acceleration]
An empty bootstrap dataset version implies that the dataset was created by the bstrap command in a version of Stata earlier than Stata 8. Here bstat expects varname [bstrap] to contain the observed value of the statistic identified by varname (varname [observed] in version 2). All other characteristics are ignored.
_dta [N] is the number of observations in the observed dataset. This characteristic may be overruled by specifying the n () option.
_dta[N_strata] is the number of strata in the observed dataset.
_dta[N_cluster] is the number of clusters in the observed dataset.
_dta[command] is the command used to compute the observed values of the statistics.
varname [observed] is the observed value of the statistic identified by varname. To specify a different value, use the stat() option.
varname[acceleration] is the estimate of acceleration for the statistic identified by varname. To specify a different value, use the accel() option.
varname [expression] is the expression or label that describes the statistic identified by varname.

## Creating a bootstrap dataset

Suppose that we are interested in obtaining bootstrap statistics by resampling the residuals from a regression (which is not possible with the bootstrap command). After loading some data, we run a regression, save some results relevant to the bstat command, and save the residuals in a new variable, res.

. matrix $b=e(b)$
. local $\mathrm{n}=\mathrm{e}(\mathrm{N})$
. predict res, residuals

We can resample the residual values in res by generating a random observation ID (rid), generate a new response variable ( y ), and run the original regression with the new response variables.

```
. set seed 54321
. generate rid = int(_N*runiform())+1
. matrix score double y = b
. replace y = y + res[rid]
(74 real changes made)
```

. regress y weight length

| Source | SS | df | MS |
| ---: | :---: | ---: | :---: |
| Model | 1695.70314 | 2 | 847.851568 |
| Residual | 601.341031 | 71 | 8.46959199 |
| Total | 2297.04417 | 73 | 31.4663585 |

| Number of obs | $=$ | 74 |
| :--- | :--- | ---: |
| F $(2,71)$ | $=$ | 100.11 |
| Prob > F | $=$ | 0.0000 |
| R-squared | $=$ | 0.7382 |
| Adj R-squared | $=$ | 0.7308 |
| Root MSE | $=$ | 2.9103 |

| y | Coefficient | Std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| weight | -.0029676 | .0013521 | -2.19 | 0.031 | -.0056636 | -.0002716 |
| length | -.1158425 | .047194 | -2.45 | 0.017 | -.2099446 | -.0217404 |
| _cons | 51.72451 | 5.190075 | 9.97 | 0.000 | 41.3758 | 62.07323 |

Instead of programming this resampling inside a loop, it is much more convenient to write a short program and use the simulate command; see [R] simulate. In the following, mysim_r requires the user to specify a coefficient vector and a residual variable. mysim_r then retrieves the list of predictor variables (removing _cons from the list), generates a new temporary response variable with the resampled residuals, and regresses the new response variable on the predictors.

```
program mysim_r
    version 18.0 // (or version 18.5 for StataNow)
    syntax name(name=bvector), res(varname)
    tempvar y rid
    local xvars : colnames 'bvector'
    local cons _cons
    local xvars : list xvars - cons
    matrix score double 'y' = 'bvector'
    generate long 'rid' = int(_N*runiform()) + 1
    replace 'y' = 'y' + 'res'['rid']
    regress 'y' 'xvars'
end
```

We can now give mysim_r a test run, but we first set the random-number seed (to reproduce results).

```
. set seed 54321
. mysim_r b, res(res)
(74 real changes made)
```

| Source | SS | df | MS |
| ---: | :---: | ---: | :---: |
| Model | 1695.70314 | 2 | 847.851568 |
| Residual | 601.341031 | 71 | 8.46959199 |
| Total | 2297.04417 | 73 | 31.4663585 |

| Number of obs | $=$ | 74 |
| :--- | :--- | ---: |
| $\mathrm{~F}(2,71)$ | $=$ | 100.11 |
| Prob > F | $=$ | 0.0000 |
| R-squared | $=$ | 0.7382 |
| Adj R-squared | $=$ | 0.7308 |
| Root MSE | $=$ | 2.9103 |

| _-000000 | Coefficient | Std. err. | t | $\mathrm{P}>\|\mathrm{tl}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | ---: | ---: |
| weight | -.0029676 | .0013521 | -2.19 | 0.031 | -.0056636 | -.0002716 |
| length | -.1158425 | .047194 | -2.45 | 0.017 | -.2099446 | -.0217404 |
| _cons | 51.72451 | 5.190075 | 9.97 | 0.000 | 41.3758 | 62.07323 |

Now that we have a program that will compute the results we want, we can use simulate to generate a bootstrap dataset and bstat to display the results.

```
. set seed 54321
. simulate, reps(200) nodots: mysim_r b, res(res)
    Command: mysim_r b, res(res)
. bstat, stat(b) n('n')
Bootstrap results Number of obs = 74
```

Replications $=200$

|  | Observed <br> coefficient | Bootstrap <br> std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ |  | Normal-based <br> [95\% conf. interval] |
| ---: | ---: | :--- | :---: | :---: | ---: | ---: |
| _b_weight | -.0038515 | .0014673 | -2.62 | 0.009 | -.0067274 | -.0009756 |
| _b_length | -.0795935 | .0509772 | -1.56 | 0.118 | -.1795069 | .0203199 |
| _b_cons | 47.88487 | 5.650947 | 8.47 | 0.000 | 36.80922 | 58.96053 |

Finally, we see that simulate created some of the data characteristics recognized by bstat. All we need to do is correctly specify the version of the bootstrap dataset, and bstat will automatically use the relevant data characteristics.

## Title

centile - Report centile and confidence interval

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| Acknowledgment | References | Also see |  |

## Description

centile estimates specified centiles and calculates confidence intervals. If no varlist is specified, centile calculates centiles for all the variables in the dataset. If no centiles are specified, medians are reported.

By default, centile uses a binomial method for obtaining confidence intervals that makes no assumptions about the underlying distribution of the variable.

## Quick start

50th percentile with $95 \%$ confidence intervals for v1 and v2
centile v1 v2
For all variables in the dataset
centile
25th, 50th, and 75th percentiles of v1
centile v1, centile (25 50 75)
10th, 20th, 30th, ..., 90th percentiles of v1
centile v1, centile(10(10)90)
Force confidence limits to fall on sample values
centile v1 v2, cci
Confidence intervals based on standard errors for a normal-distribution quantile
centile v1 v2, normal
Centile and confidence intervals based on mean and standard deviation
centile v1 v2, meansd
Replace data in memory with centiles for groups defined by categorical variable cvar
statsby, by (cvar) clear: centile v1, centile(25 50 75)

## Menu

Statistics $>$ Summaries, tables, and tests $>$ Summary and descriptive statistics $>$ Centiles with Cls

## Syntax

$$
\text { centile }[\text { varlist }][\text { if }][\text { in }][, \text { options }]
$$

options
Main
centile(numlist)
Options
cci
normal
meansd
level(\#)

Description
report specified centiles; default is centile(50)
binomial exact; conservative confidence interval normal, based on observed centiles
normal, based on mean and standard deviation
set confidence level; default is level (95)
by, collect, and statsby are allowed; see [U] 11.1.10 Prefix commands.

## Options

$\qquad$
centile(numlist) specifies the centiles to be reported. The default is to display the 50th centile. Specifying centile(5) requests that the fifth centile be reported. Specifying centile (5 50 95 ) requests that the 5 th, 50 th, and 95 th centiles be reported. Specifying centile (10 (10) 90) requests that the 10 th, 20 th, $\ldots, 90$ th centiles be reported; see [U] 11.1.8 numlist.

Options
cci (conservative confidence interval) forces the confidence limits to fall exactly on sample values. Confidence intervals displayed with the cci option are slightly wider than those with the default (nocci) option.
normal causes the confidence interval to be calculated by using a formula for the standard error of a normal-distribution quantile given by Kendall and Stuart (1969, 237). The normal option is useful when you want empirical centiles - that is, centiles based on sample order statistics rather than on the mean and standard deviation - and are willing to assume normality.
meansd causes the centile and confidence interval to be calculated based on the sample mean and standard deviation, and it assumes normality.
level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [R] level.

## Remarks and examples

The $q$ th centile of a continuous random variable, $X$, is defined as the value of $C_{q}$, which fulfills the condition $\operatorname{Pr}\left(X \leq C_{q}\right)=q / 100$. The value of $q$ must be in the range $0<q<100$, though $q$ is not necessarily an integer. By default, centile estimates $C_{q}$ for the variables in varlist and for the values of $q$ given in centile (numlist). It makes no assumptions about the distribution of $X$ and, if necessary, uses linear interpolation between neighboring sample values. Extreme centiles (for example, the 99th centile in samples smaller than 100) are fixed at the minimum or maximum sample value. An "exact" confidence interval for $C_{q}$ is also given, using the binomial-based method described below in Methods and formulas and in Conover (1999, 143-148). Again linear interpolation is used to improve the accuracy of the estimated confidence limits, but extremes are fixed at the minimum or maximum sample value.

You can prevent centile from interpolating when calculating binomial-based confidence intervals by specifying cci. The resulting intervals are generally wider than with the default; that is, the coverage (confidence level) tends to be greater than the nominal value (given as usual by level(\#), by default $95 \%$ ).

If the data are believed to be normally distributed (a common case), there are two alternative methods for estimating centiles. If normal is specified, $C_{q}$ is calculated, as just described, but its confidence interval is based on a formula for the standard error (se) of a normal-distribution quantile given by Kendall and Stuart (1969, 237). If meansd is alternatively specified, $C_{q}$ is estimated as $\bar{x}+z_{q} \times s$, where $\bar{x}$ and $s$ are the sample mean and standard deviation, respectively, and $z_{q}$ is the $q$ th centile of the standard normal distribution (for example, $z_{95}=1.645$ ). The confidence interval is derived from the se of the estimate of $C_{q}$.

## Example 1

Using auto.dta, we estimate the 5th, 50th, and 95th centiles of the price variable:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. format price %8.2fc
. centile price, centile(5 50 95)
```

| Variable | Obs | Percentile | Centile | Binom. interp. |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
|  | [95\% conf. interval] |  |  |  |  |
| price | 74 | 5 | $3,727.75$ | $3,291.23$ | $3,914.16$ |
|  |  | 50 | $5,006.50$ | $4,593.57$ | $5,717.90$ |
|  |  | 95 | $13,498.00$ | $11,061.53$ | $15,865.30$ |

summarize produces somewhat different results from centile; see Methods and formulas.
. summarize price, detail
Price

|  | Percentiles | Smallest |  |  |
| ---: | ---: | ---: | :--- | ---: |
| $1 \%$ | 3291 | 3291 |  | 74 |
| $5 \%$ | 3748 | 3299 |  | 74 |
| $10 \%$ | 3895 | 3667 | Obs |  |
| $25 \%$ | 4195 | 3748 | Sum of wgt. |  |
| $50 \%$ | 5006.5 |  | Mean | 6165.257 |
|  |  | Largest | Std. dev. | 2949.496 |
| $75 \%$ | 6342 | 13466 |  | 8699526 |
| $90 \%$ | 11385 | 13594 | Variance | 1.653434 |
| $95 \%$ | 13466 | 14500 | Skewness | 1.3 |
| $99 \%$ | 15906 | 15906 | Kurtosis | 4.819188 |

The confidence limits produced by using the cci option are slightly wider than those produced without this option:

```
. centile price, c(5 50 95) cci
```

| Variable | Obs | Percentile | Centile | Binomial exact <br> [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| price | 74 | 5 | $3,727.75$ | $3,291.00$ | $3,955.00$ |
|  |  | 50 | $5,006.50$ | $4,589.00$ | $5,719.00$ |
|  |  | 95 | $13,498.00$ | $10,372.00$ | $15,906.00$ |

If we are willing to assume that price is normally distributed, we could include either the normal or the meansd option:

```
. centile price, c(5 50 95) normal
```

| Variable | - Normal, based on observed centiles - |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
|  | Obs | Percentile | Centile | [95\% conf. interval] |  |
| price | 74 | 5 | $3,727.75$ | $3,211.19$ | $4,244.31$ |
|  |  | 50 | $5,006.50$ | $4,096.68$ | $5,916.32$ |
|  |  | 95 | $13,498.00$ | $5,426.81$ | $21,569.19$ |

. centile price, c(5 50 95) meansd

| Variable | Obs | Percentile | Normal, based on mean and std. dev. Centile <br> [95\% conf. interval] |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| price | 74 | 5 | 1,313.77 | 278.93 | 2,348.61 |
|  |  | 50 | 6,165.26 | 5,493.24 | 6,837.27 |
|  |  | 95 | 11,016.75 | 9,981.90 | 12,051.59 |

With the normal option, the centile estimates are, by definition, the same as before. The confidence intervals for the 5th and 50th centiles are similar to the previous ones, but the interval for the 95th centile is different. The results using the meansd option also differ from both previous sets of estimates.

We can use sktest (see [R] sktest) to check the correctness of the normality assumption:
. sktest price
Skewness and kurtosis tests for normality

| Variable | Obs | $\operatorname{Pr}$ (skewness) | Pr(kurtosis) | Adj chi2(2) | Prob>chi2 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| price | 74 | 0.0000 | 0.0127 | 21.77 | 0.0000 |

sktest reveals that price is definitely not normally distributed, so the normal assumption is not reasonable, and the normal and meansd options are not appropriate for these data. We should rely on the results from the default choice, which does not assume normality. If the data are normally distributed, however, the precision of the estimated centiles and their confidence intervals will be ordered (best) meansd > normal > [default] (worst). The normal option is useful when we really do want empirical centiles (that is, centiles based on sample order statistics rather than on the mean and standard deviation) but are willing to assume normality.

## Stored results

centile stores the following in $r()$ :
Scalars
$r(N) \quad$ number of observations
$r$ (n_cent) number of centiles requested
r(c_\#) value of \# centile
r(lb_\#) \#-requested centile lower confidence bound
r(ub_\#) \#-requested centile upper confidence bound
Macros
r(centiles) centiles requested

## Methods and formulas

Methods and formulas are presented under the following headings:
Default case
Normal case
meansd case

## Default case

The calculation is based on the method of Mood and Graybill (1963, 408). Let $x_{1} \leq x_{2} \leq \cdots \leq x_{n}$ be a sample of size $n$ arranged in ascending order. Denote the estimated $q$ th centile of the $x$ 's as $c_{q}$. We require that $0<q<100$. Let $R=(n+1) q / 100$ have integer part $r$ and fractional part $f$; that is, $r=\operatorname{int}(R)$ and $f=R-r$. (If $R$ is itself an integer, then $r=R$ and $f=0$.) Note that $0 \leq r \leq n$. For convenience, define $x_{0}=x_{1}$ and $x_{n+1}=x_{n} . C_{q}$ is estimated by

$$
c_{q}=x_{r}+f \times\left(x_{r+1}-x_{r}\right)
$$

that is, $c_{q}$ is a weighted average of $x_{r}$ and $x_{r+1}$. Loosely speaking, a (conservative) $p \%$ confidence interval for $C_{q}$ involves finding the observations ranked $t$ and $u$, which correspond, respectively, to the $\alpha=(100-p) / 200$ and $1-\alpha$ quantiles of a binomial distribution with parameters $n$ and $q / 100$, that is, $\mathrm{B}(n, q / 100)$. More precisely, define the $i$ th value $(i=0, \ldots, n$ ) of the cumulative binomial distribution function as $F_{i}=\operatorname{Pr}(S \leq i)$, where $S$ has distribution $B(n, q / 100)$. For convenience, let $F_{-1}=0$ and $F_{n+1}=1 . t$ is found such that $F_{t} \leq \alpha$ and $F_{t+1}>\alpha$, and $u$ is found such that $1-F_{u} \leq \alpha$ and $1-F_{u-1}>\alpha$.

With the cci option in force, the (conservative) confidence interval is $\left(x_{t+1}, x_{u+1}\right)$, and its actual coverage probability is $F_{u}-F_{t}$.

The default case uses linear interpolation on the $F_{i}$ as follows. Let

$$
\begin{aligned}
g & =\left(\alpha-F_{t}\right) /\left(F_{t+1}-F_{t}\right) \\
h & =\left\{\alpha-\left(1-F_{u}\right)\right\} /\left\{\left(1-F_{u-1}\right)-\left(1-F_{u}\right)\right\} \\
& =\left(\alpha-1+F_{u}\right) /\left(F_{u}-F_{u-1}\right)
\end{aligned}
$$

The interpolated lower and upper confidence limits $\left(c_{q L}, c_{q U}\right)$ for $C_{q}$ are

$$
\begin{aligned}
c_{q L} & =x_{t+1}+g \times\left(x_{t+2}-x_{t+1}\right) \\
c_{q U} & =x_{u+1}-h \times\left(x_{u+1}-x_{u}\right)
\end{aligned}
$$

Suppose that we want a $95 \%$ confidence interval for the median of a sample of size $13 . n=13$, $q=50, p=95, \alpha=0.025, R=14 \times 50 / 100=7$, and $f=0$. Therefore, the median is the 7th observation. Some example data, $x_{i}$, and the values of $F_{i}$ are as follows:

| $i$ | $F_{i}$ | $1-F_{i}$ | $x_{i}$ | $i$ | $F_{i}$ | $1-F_{i}$ | $x_{i}$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 0.0001 | 0.9999 | - | 7 | 0.7095 | 0.2905 | 33 |
| 1 | 0.0017 | 0.9983 | 5 | 8 | 0.8666 | 0.1334 | 37 |
| 2 | 0.0112 | 0.9888 | 7 | 9 | 0.9539 | 0.0461 | 45 |
| 3 | 0.0461 | 0.9539 | 10 | 10 | 0.9888 | 0.0112 | 59 |
| 4 | 0.1334 | 0.8666 | 15 | 11 | 0.9983 | 0.0017 | 77 |
| 5 | 0.2905 | 0.7095 | 23 | 12 | 0.9999 | 0.0001 | 104 |
| 6 | 0.5000 | 0.5000 | 28 | 13 | 1.0000 | 0.0000 | 211 |

The median is $x_{7}=33$. Also, $F_{2} \leq 0.025$ and $F_{3}>0.025$, so $t=2 ; 1-F_{10} \leq 0.025$ and $1-F_{9}>0.025$, so $u=10$. The conservative confidence interval is therefore

$$
\left(c_{50 L}, c_{50 U}\right)=\left(x_{t+1}, x_{u+1}\right)=\left(x_{3}, x_{11}\right)=(10,77)
$$

with actual coverage $F_{10}-F_{2}=0.9888-0.0112=0.9776$ ( $97.8 \%$ confidence). For the interpolation calculation, we have

$$
\begin{aligned}
& g=(0.025-0.0112) /(0.0461-0.0112)=0.395 \\
& h=(0.025-1+0.9888) /(0.9888-0.9539)=0.395
\end{aligned}
$$

So,

$$
\begin{array}{r}
c_{50 L}=x_{3}+0.395 \times\left(x_{4}-x_{3}\right)=10+0.395 \times 5=11.98 \\
c_{50 U}=x_{11}-0.395 \times\left(x_{11}-x_{10}\right)=77-0.395 \times 18=69.89
\end{array}
$$

## Normal case

The value of $c_{q}$ is as above. Its se is given by the formula

$$
s_{q}=\sqrt{q(100-q)} /\left\{100 \sqrt{n} Z\left(c_{q} ; \bar{x}, s\right)\right\}
$$

where $\bar{x}$ and $s$ are the mean and standard deviation of the $x_{i}$, and

$$
Z(Y ; \mu, \sigma)=\left(1 / \sqrt{2 \pi \sigma^{2}}\right) e^{-(Y-\mu)^{2} / 2 \sigma^{2}}
$$

is the density function of a normally distributed variable $Y$ with mean $\mu$ and standard deviation $\sigma$. The confidence interval for $C_{q}$ is $\left(c_{q}-z_{100(1-\alpha)} s_{q}, c_{q}+z_{100(1-\alpha)} s_{q}\right)$.

## meansd case

The value of $c_{q}$ is $\bar{x}+z_{q} \times s$. Its se is given by the formula

$$
s_{q}^{\star}=s \sqrt{1 / n+z_{q}^{2} /(2 n-2)}
$$

The confidence interval for $C_{q}$ is $\left(c_{q}-z_{100(1-\alpha)} \times s_{q}^{\star}, c_{q}+z_{100(1-\alpha)} \times s_{q}^{\star}\right)$.

## Title

churdle - Cragg hurdle regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

churdle fits a linear or exponential hurdle model for a bounded dependent variable. The hurdle model combines a selection model that determines the boundary points of the dependent variable with an outcome model that determines its nonbounded values. Separate independent covariates are permitted for each model.

## Quick start

Linear hurdle model of y 1 on x 1 and x 2 , specifying that y 1 is truncated at 0 with x 1 and x 3 predicting selection

```
churdle linear y1 x1 x2, select(x1 x3) ll(0)
```

Add an upper truncation limit of 40

```
churdle linear y1 x1 x2, select(x1 x3) ll(0) ul(40)
```

Same as above, with the upper truncation limit specified in trunc

```
churdle linear y1 x1 x2, select(x1 x3) ll(0) ul(trunc)
```

Same as above, and use $x 3$ to model the variance of the selection model

```
churdle linear y1 x1 x2, select(x1 x3, het(x3)) ll(0) ul(trunc)
```

Same as above, and use $x 4$ to model the variance of the outcome model

```
churdle linear y1 x1 x2, select(x1 x3, het(x3)) ll(0) ///
    ul(trunc) het(x4)
```

Exponential hurdle model of y 2 on x 1 and x 2 , specifying that y 2 is truncated at 4 with x 1 and x 3 predicting selection

```
churdle exponential y2 x1 x2, select(x1 x3) ll(4)
```

## Menu

Statistics $>$ Linear models and related $>$ Hurdle regression

## Syntax

Basic syntax

```
churdle linear depvar, select(varlists) {ll(...)|ul(...)}
churdle exponential depvar, select(varlists) ll(...)

upper truncation limit
suppress constant term
apply specified linear constraints
specify variables to model the variance
vcetype may be oim, robust, cluster clustvar, bootstrap, or jackknife
set confidence level; default is level (95)
do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

Maximization
maximize_options
coeflegend
control the maximization process; seldom used
display legend instead of statistics
*select () is required.
The full specification is select (varlist $\left[\right.$, noconstant het (varlist ${ }_{o}$ )]).
noconstant specifies that the constant be excluded from the selection model.
het $\left(\right.$ varlist $\left._{o}\right)$ specifies the variables in the error-variance function of the selection model.
$\ddagger_{\text {You must specify at least one of ul(\#|varname) or } 11(\# \mid \text { varname) for the linear model and must specify }}$ 11 (\#|varname) for the exponential model.
indepvars, varlist $_{s}$, and varlist ${ }_{O}$ may contain factor variables; see [U] 11.4.3 Factor variables.
bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

$\qquad$ Model
select (varlist $\left[\right.$, noconstant het $\left(\right.$ varlist $\left.\left.\left._{o}\right)\right]\right)$ specifies the variables and options for the selection model. select () is required.
11 (\#|varname) and ul(\#|varname) indicate the lower and upper limits, respectively, for the dependent variable. You must specify one or both for the linear model and must specify a lower limit for the exponential model. Observations with depvar $\leq 11$ () have a lower bound; observations with depvar $\geq \mathrm{ul}$ () have an upper bound; and the remaining observations are in the continuous region.
noconstant, constraints (constraints); see [R] Estimation options.
het (varlist) specifies the variables in the error-variance function of the outcome model.

## SE/Robust

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster, clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vee_option.

## Reporting

level(\#), nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% fint), and nolstretch; see [R] Estimation options.

Maximization
maximize_options: difficult, technique (algorithm_spec), iterate(\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance(\#), nonrtolerance, and from (init_specs); see [R] Maximize. These options are seldom used.

The following option is available with churdle but is not shown in the dialog box: coeflegend; see [R] Estimation options.

## Remarks and examples

churdle fits a linear or an exponential hurdle model. It combines a selection model that determines the boundary points of the dependent variable with an outcome model that determines its nonbounded values. Hurdle models treat these boundary values as observed instead of censored. That is to say, observations where the dependent variable is equal to one of the boundary values are not the result of our inability to observe the distribution above or below a certain point; see Wooldridge (2010) chapter 17 for a thorough discussion of this point.

These models were proposed by Cragg (1971) to explain the demand for durable goods. In the Cragg model, individuals purchase zero or a positive amount of the durable good, with different factors determining each of these choices. This may be generalized to other individual decisions, such as money donated to charity, cigarette consumption, and time spent volunteering.

Hurdle models are characterized by the relationship $y_{i}=s_{i} h_{i}^{*}$, where $y_{i}$ is the observed value of the dependent variable.

The selection variable, $s_{i}$, is 1 if the dependent variable is not bounded and 0 otherwise. In the Cragg model, the lower limit that binds the dependent variable is 0 so the selection model is

$$
s_{i}= \begin{cases}1 & \text { if } \mathbf{z}_{i} \gamma+\epsilon_{i}>0 \\ 0 & \text { otherwise }\end{cases}
$$

where $\mathbf{z}_{i}$ is a vector of explanatory variables, $\gamma$ is a vector of coefficients, and $\epsilon_{i}$ is a standard normal error term. churdle allows a different lower limit to be specified in 11 () and, for the linear model, an upper limit in ul(). Conditional heteroskedasticity of the random error $\epsilon_{i}$ is allowed if suboption het () is specified in select().

The continuous latent variable $h_{i}^{*}$ is observed only if $s_{i}=1$. The outcome model can be either the linear model or the exponential model, as proposed in Cragg (1971):

$$
\begin{aligned}
& h_{i}^{*}=\mathbf{x}_{i} \boldsymbol{\beta}+\nu_{i} \\
& h_{i}^{*}=\exp \left(\mathbf{x}_{i} \boldsymbol{\beta}+\nu_{i}\right) \quad \text { (exponential) }
\end{aligned}
$$

where $\mathbf{x}_{i}$ is a vector of explanatory variables, $\boldsymbol{\beta}$ is a vector of coefficients, and $\nu_{i}$ is an error term.
For the linear model, $\nu_{i}$ has a truncated normal distribution with lower truncation point $-\mathbf{x}_{i} \boldsymbol{\beta}$. For the exponential model, $\nu_{i}$ has a normal distribution. churdle extends the Cragg hurdle models to allow for conditional heteroskedasticity of the random error $\nu_{i}$ if the user specifies the het () option.

The parameters and regressors in the models for $h_{i}^{*}$ and for $s_{i}$ may differ.
> Example 1: Linear hurdle model
Consider a dataset that contains the number of hours an individual exercises per day (hours), their age (age), whether they are single (single), hours they work per day (whours), whether they smoke (smoke), their weight in kilograms (weight), their distance from the nearest gym (distance), and their average commute from work (commute).

Figure 1.
Figure 1 shows that $43.9 \%$ of the individuals in the sample do not exercise and that the hours exercised varies among individuals that decide to exercise.

We model the decision to exercise or not as a function of commute, whours, and age. These variables are written in select(). Once a decision to exercise is made, the time an individual exercises is modeled as a linear function of age, smoke, distance, and single.

```
. use https://www.stata-press.com/data/r18/fitness
(Fictional fitness data)
. churdle linear hours age i.smoke distance i.single,
> select(commute whours age) ll(0)
Iteration 0: Log likelihood = -23657.236
Iteration 1: Log likelihood = -23344.182
Iteration 2: Log likelihood = -23340.051
Iteration 3: Log likelihood = -23340.044
Iteration 4: Log likelihood = -23340.044
Cragg hurdle regression Number of obs = 19,831

| age | -. 0485347 | . 0006501 | -74.65 | 0.000 | -. 049809 | -. 0472604 |
| _cons | 2.649945 | . 0499795 | 53.02 | 0.000 | 2.551987 | 2.747903 |
| lnsigma |  |  |  |  |  |  |
| _cons | . 0083199 | . 0099648 | 0.83 | 0.404 | -. 0112107 | . 0278506 |
| /sigma | 1.008355 | . 010048 |  |  | . 9888519 | 1.028242 |

The coefficients in the outcome model for the latent variable appear under hours. Because we only specified a lower limit to bind the dependent variable, the output shows parameter estimates for a single selection model under selection_ll. Information about the estimated standard deviation of the error term in the outcome model appears under lnsigma and /sigma.

The coefficient estimates are not directly interpretable. To obtain the effect of a covariate on the model, we need to use the margins command; see [R] churdle postestimation. Consider the effect of age:
. margins, dydx(age)
Average marginal effects $\quad$ Number of obs $=19,831$
Model VCE: OIM
Expression: Conditional mean estimates of dependent variable, predict()
dy/dx wrt: age

|  | Delta-method |  |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
|  | dy/dx | std. err. | z | P>\|z| | [95\% conf. interval] |  |
| age | -.0216855 | .000289 | -75.03 | 0.000 | -.022252 | -.021119 |

Each additional year of age is associated with about -0.02 fewer hours, or 1.2 minutes, of exercise.

## $>$ Example 2: Linear hurdle with models for the outcome and selection variances

In this example, we illustrate the possibility of fitting a heteroskedastic probit for the selection and latent model. In both cases, this is done by specifying age and single as the variables that affect the conditional variance. As in example 1, we have separate parameters for the outcome model and lower-limit selection model.
. churdle linear hours age i.smoke distance i.single,
> select(commute whours age, het(age single)) ll(0) het(age single) nolog
Cragg hurdle regression

Log likelihood $=-23339.355$$\quad$ Number of obs $=19,831$

| hours | Coefficient | Std. err. | z | $P>\|z\|$ | [95\% con | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| hours |  |  |  |  |  |  |
| age | . 0012559 | . 0008198 | 1.53 | 0.126 | -. 0003508 | . 0028626 |
| smoke |  |  |  |  |  |  |
| Smoking | -1.065564 | . 0457657 | -23.28 | 0.000 | -1.155263 | -. 9758649 |
| distance | -. 1332939 | . 0126102 | -10.57 | 0.000 | -. 1580094 | -. 1085783 |
| single |  |  |  |  |  |  |
| Single | 1.002511 | . 032535 | 30.81 | 0.000 | . 9387436 | 1.066278 |
| _cons | . 9166356 | . 0388318 | 23.61 | 0.000 | . 8405268 | . 9927445 |
| selection_ll |  |  |  |  |  |  |
| commute | -. 2959986 | . 0641594 | -4.61 | 0.000 | -. 4217488 | -. 1702484 |
| whours | . 0024514 | . 0069769 | 0.35 | 0.725 | -. 0112231 | . 0161259 |
| age | -. 048886 | . 0021405 | -22.84 | 0.000 | -. 0530814 | -. 0446906 |
| _cons | 2.669613 | . 1139478 | 23.43 | 0.000 | 2.44628 | 2.892947 |
| Insigma |  |  |  |  |  |  |
| age | . 0003537 | . 0004026 | 0.88 | 0.380 | -. 0004354 | . 0011427 |
| single | -. 0080667 | . 019253 | -0.42 | 0.675 | -. 0458019 | . 0296685 |
| lnsigma_ll |  |  |  |  |  |  |
| age | -. 0002035 | . 0008424 | -0.24 | 0.809 | -. 0018546 | . 0014475 |
| single | . 0268271 | . 0270133 | 0.99 | 0.321 | -. 0261179 | . 0797721 |

The coefficients on age and single have no effect on the conditional variance of the outcome model or on the conditional variance of the selection model. Thus, there is no evidence that the variance depends on age and marital status.

## > Example 3: Exponential hurdle model

Returning to example 1, if we believe that the conditional mean of the latent variable has an exponential form instead of a linear form, we use churdle exponential.
. churdle exponential hours age i.smoke distance i.single,
$>$ select(commute whours age) ll(0) nolog
Cragg hurdle regression

Log likelihood $=-15666.195$$\quad$| Number of obs $=19,831$ |
| :--- |

| hours | Coefficient | Std. err | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| hours |  |  |  |  |  |  |
| age | . 0008368 | . 0005341 | 1.57 | 0.117 | -. 00021 | . 0018836 |
| smoke |  |  |  |  |  |  |
| Smoking | -. 6431348 | . 0258509 | -24.88 | 0.000 | -. 6938016 | -. 592468 |
| distance | -. 0772879 | . 0079132 | -9.77 | 0.000 | -. 0927976 | -. 0617783 |
| single |  |  |  |  |  |  |
| Single | . 5975111 | . 016108 | 37.09 | 0.000 | . 5659401 | . 6290821 |
| _cons | -. 0770619 | . 0254833 | -3.02 | 0.002 | -. 1270082 | -. 0271157 |
| selection_11 |  |  |  |  |  |  |
| commute | -. 2953345 | . 0624665 | -4.73 | 0.000 | -. 4177666 | -. 1729024 |
| whours | . 0022974 | . 0069306 | 0.33 | 0.740 | -. 0112864 | . 0158811 |
| age | -. 0485347 | . 0006501 | -74.65 | 0.000 | -. 049809 | -. 0472604 |
| _cons | 2.649945 | . 0499795 | 53.02 | 0.000 | 2.551987 | 2.747903 |
| lnsigma |  |  |  |  |  |  |
| _cons | -. 186917 | . 0067067 | -27.87 | 0.000 | -. 200062 | -. 1737721 |
| /sigma | . 8295126 | . 0055633 |  |  | . 81868 | . 8404884 |

What was said previously regarding the interpretation of the effects of the different regressors also holds true for churdle exponential. We again use margins to estimate the effect of age on time spent exercising.

| Average marginal effects Model VCE: OIM |  |  | Number of obs $=19,831$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Expression: Conditional mean estimates of dependent variable, predict() dy/dx wrt: age |  |  |  |  |  |  |
|  | dy/dx | lta-meth std. err | z | $P>\|z\|$ | [95\% conf | interval] |
| age | -. 0245582 | . 0004805 | -51.11 | 0.000 | -. 0255 | -. 0236164 |

With the exponential outcome model of the latent variable, our estimate is that each additional year of age decreases exercise time by about 0.025 hours, or 1.5 minutes.

## Stored results

churdle stores the following in e():
Scalars

```
e(N)
e(k_eq_model)
e(df_m)
e(r2_p)
e(chi2)
e(ll)
e(1l_0)

In addition to the above, the following is stored in r() :

Matrices
$r$ (table)
matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

Let $\ell \ell$ refer to the lower limit and $u \ell$ to the upper limit. Also let the probabilities of being at these limits be given by

$$
\begin{aligned}
\operatorname{Pr}\left(y_{i}\right. & \left.=\ell \ell \mid \mathbf{z}_{i}\right)
\end{aligned}=\Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \gamma_{\ell \ell}\right), ~=\Phi\left(\mathbf{z}_{i}^{\prime} \gamma_{u \ell}-u \ell\right) .
$$

where $\mathbf{z}_{i}$ are the covariates of the selection model for individual $i$, which may be distinct from the covariates $\mathbf{x}_{i}$ for the latent model; $\mathbf{\Phi}$ corresponds to the standard normal cumulative distribution function; $\gamma_{\ell \ell}$ is the parameter vector for the lower-limit selection model; and $\gamma_{u \ell}$ is the parameter vector for the upper-limit selection model.

Under the assumptions that $\nu_{i}$ has a truncated normal distribution with lower truncation point $\ell \ell-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}$ and upper truncation point $u \ell-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}$ and has a homoskedastic variance, the log-likelihood function is given by

$$
\begin{aligned}
\ln \mathbf{L}= & \sum_{i=1}^{n}\left(y_{i} \leq \ell \ell\right) \log \Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{\ell \ell}\right)+\left(y_{i} \geq u \ell\right) \log \left\{1-\Phi\left(u \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{u \ell}\right)\right\} \\
& +\left(u \ell>y_{i}>\ell \ell\right)\left[\log \left\{\Phi\left(u \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{u \ell}\right)-\Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{\ell \ell}\right)\right\}\right] \\
& -\left(u \ell>y_{i}>\ell \ell\right)\left[\log \left\{\Phi\left(\frac{u \ell-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)-\Phi\left(\frac{\ell \ell-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)\right\}\right] \\
& +\left(u \ell>y_{i}>\ell \ell\right)\left[\log \left\{\phi\left(\frac{y_{i}-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)\right\}-\log (\sigma)\right]
\end{aligned}
$$

Without the homoskedasticity assumption, the heteroskedasticity can be modeled using the form $\sigma^{2}\left(\mathbf{w}_{i}\right)=\exp \left(2 \mathbf{w}_{i}^{\prime} \boldsymbol{\theta}\right)$, where $\mathbf{w}_{i}$ are the variables that affect the conditional variance of $\nu_{i}$. The $\log$-likelihood function is obtained by replacing $\sigma$ with $\exp \left(\mathbf{w}_{i}^{\prime} \boldsymbol{\theta}\right)$.

The log-likelihood function for the exponential model is given by

$$
\begin{aligned}
\ln \mathbf{L}= & \sum_{i=1}^{n}\left(y_{i} \leq \ell \ell\right) \log \Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}\right)+\left(y_{i}>\ell \ell\right)\left[\log \left\{1-\Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}\right)\right\}\right] \\
& \left.+\left(y_{i}>\ell \ell\right)\left\{\log \left\{\boldsymbol{\phi}\left[\log \left(y_{i}-\ell \ell\right)-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}\right) / \sigma\right]\right\}-\log (\sigma)-\log \left(y_{i}-\ell \ell\right)\right\}
\end{aligned}
$$

Analogous to the linear case, we can model heteroskedasticity by $\sigma^{2}\left(\mathbf{w}_{i}\right)=\exp \left(2 \mathbf{w}_{i}^{\prime} \boldsymbol{\theta}\right)$.
Estimation of both of the aforementioned likelihood functions is done by maximum likelihood.

## Title

churdle postestimation - Postestimation tools for churdle

| Postestimation commands | predict | margins |
| :--- | :--- | :--- |
| Remarks and examples | Methods and formulas | Also see |

## Postestimation commands

The following standard postestimation commands are available after churdle:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estat (svy) | postestimation statistics for survey data |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| * forecast | dynamic forecasts and simulations |
| * hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| * 1 rtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | conditional means, residuals, etc. |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| suest | seemingly unrelated estimation |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

[^9]
## predict

## Description for predict

predict creates a new variable containing predictions such as conditional expectation of depvar, residuals, linear predictions, standard errors, and probabilities.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic equation(eqno)]
predict [type] stub* [if] [in], scores
```

## statistic <br> Description

## Main

| ystar | conditional expectation of depvar; the default |
| :--- | :--- |
| $\underline{\text { residuals }}$ | residuals |
| $\mathrm{ys} \operatorname{star}(a, b)$ | $E\left(y_{j}^{*}\right), y_{j}^{*}=\max \left\{a, \min \left(y_{j}, b\right)\right\}$ |
| xb | linear prediction |
| stdp | standard error of the linear prediction |
| $\operatorname{pr}(a, b)$ | $\operatorname{Pr}\left(a<y_{j}<b\right)$ |
| $\mathrm{e}(a, b)$ | $E\left(y_{j} \mid a<y_{j}<b\right)$ |

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.
where $a$ and $b$ may be numbers or variables; $a$ missing ( $a \geq$.) means $-\infty$, and $b$ missing ( $b \geq$.) means $+\infty$; see [U] 12.2.1 Missing values. For churdle exponential, $b$ is . (missing).

## Options for predict

Main
ystar, the default, calculates the conditional expectation of the dependent variable.
residuals calculates the residuals.
ystar $(a, b)$ calculates $E\left(y_{j}^{*}\right) . a$ and $b$ are specified as they are for $\operatorname{pr}()$. If $a$ and $b$ are equal to the lower and upper bounds specified in churdle, then $E\left(y_{j}^{*}\right)$ is equivalent to the predicted value of the dependent variable ystar.
xb calculates the linear prediction.
stdp calculates the standard error of the linear prediction.
$\operatorname{pr}(a, b)$ calculates $\operatorname{Pr}\left(a<y_{j}<b\right)$, the probability that $y_{j} \mid \mathbf{x}_{i}$ would be observed in the interval $(a, b)$.
$a$ and $b$ may be specified as numbers or variable names; $l b$ and $u b$ are variable names;
$\operatorname{pr}(20,30)$ calculates $\operatorname{Pr}\left(20<y_{j}<30\right) ; \operatorname{pr}(l b, u b)$ calculates $\operatorname{Pr}\left(l b<y_{j}<u b\right)$;
and $\operatorname{pr}(20, u b)$ calculates $\operatorname{Pr}\left(20<y_{j}<u b\right)$.
$a$ missing $(a \geq$.$) means 11 ; \operatorname{pr}(., 30)$ calculates $\operatorname{Pr}\left(l l<y_{j}<30\right)$;
$\operatorname{pr}(l b, 30)$ calculates $\operatorname{Pr}\left(l l<y_{j}<30\right)$ in observations for which $l b \geq$. and calculates $\operatorname{Pr}\left(l b<y_{j}<30\right)$ elsewhere.
$b$ missing ( $b \geq$. ) means $\infty$; $\operatorname{pr}(20,$.$) calculates \operatorname{Pr}\left(\infty>y_{j}>20\right)$;
$\operatorname{pr}(20, u b)$ calculates $\operatorname{Pr}\left(\infty>y_{j}>20\right)$ in observations for which $u b \geq$. and calculates $\operatorname{Pr}\left(u b>y_{j}>20\right)$ elsewhere. For churdle linear, $u l$ is $\infty$.
$\mathrm{e}(a, b)$ calculates $E\left(y_{j} \mid a<y_{j}<b\right)$, the expected value of $y_{j} \mid \mathbf{x}_{j}$ conditional on $y_{j} \mid \mathbf{x}_{j}$ being in the interval $(a, b)$, meaning that $y_{j} \mid \mathbf{x}_{j}$ is bounded. $a$ and $b$ are specified as they are for pr() .
equation (eqno) specifies the equation for which predictions are to be made for the xb and stdp options. equation() should contain either one equation name or one of \#1, \#2, ... with \#1 meaning the first equation, \#2 meaning the second equation, etc.

If you do not specify equation(), the results are the same as if you specified equation(\#1).
scores calculates the equation-level score variables. If you specify one new variable, the scores for the latent-variable equation are computed. If you specify a variable list, the scores for each equation are calculated. The following scores may be obtained:
the first new variable will contain $\partial \ln L / \partial\left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$,
the second new variable will contain $\partial \ln L / \partial\left(\mathbf{z}_{j} \gamma_{l l}\right)$,
the third new variable will contain $\partial \ln L / \partial\left(\mathbf{z}_{j} \gamma_{u l}\right)$,
the fourth new variable will contain $\partial \ln L / \partial(\sigma)$,
the fifth new variable will contain $\partial \ln L / \partial\left(\sigma_{l l}\right)$, and
the sixth new variable will contain $\partial \ln L / \partial\left(\sigma_{u l}\right)$.

## margins

## Description for margins

margins estimates margins of response for conditional expectations, linear predictions, and probabilities.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic
Description
Main

| ystar | conditional expectation of depvar; the default |
| :--- | :--- |
| $\frac{\mathrm{ys}}{\mathrm{xb}} \mathrm{tar}(a, b)$ | $E\left(y_{j}^{*}\right), y_{j}^{*}=\max \left\{a, \min \left(y_{j}, b\right)\right\}$; for churdle exponential $b$ is. |
| $\mathrm{pr}(a, b)$ | linear prediction |
| $\mathrm{e}(a, b)$ | $\operatorname{Pr}\left(a<y_{j}<b\right) ;$ for churdle exponential $b$ is. |
| residuals | $E\left(y_{j} \mid a<y_{j}<b\right) ;$ for churdle exponential $b$ is. |
| stdp | not allowed with margins |
|  | not allowed with margins |

Statistics not allowed with margins are functions of stochastic quantities other than e(b). For the full syntax, see [R] margins.

## Remarks and examples

$>$ Example 1: Predictions for depvar
Below, we use the parameters estimated in example 1 of $[\mathrm{R}]$ churdle to calculate the average hours exercised given the covariates.

```
. use https://www.stata-press.com/data/r18/fitness
(Fictional fitness data)
. churdle linear hours age i.smoke distance i.single,
> select(commute whours age) ll(0)
    (output omitted)
. predict hourshat
(statistic ystar assumed)
```

We might also be interested in estimating the average number of hours exercised given that an individual exercises. Below we estimate this quantity and compare it with the predicted and true values of the dependent variable for all the observations.

- predict exercises, e(0,.)
. summarize hours hourshat exercises

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| hours | 19,831 | .8800172 | 1.051221 | 0 | 5.308835 |
| hourshat | 19,831 | .8786302 | .4915214 | .0754708 | 1.904694 |
| exercises | 19,831 | 1.580729 | .3998335 | .5630298 | 2.079012 |

As expected, we observe that the sample-average predictions are higher for those who exercise.

## > Example 2: Marginal effects

Suppose we want to study whether single individuals exercise more on average than married individuals. Below, we use margins to estimate the average effect of being single on hours spent exercising in the population.

```
. margins, dydx(1.single)
Average marginal effects Number of obs = 19,831
Model VCE: OIM
Expression: Conditional mean estimates of dependent variable, predict()
dy/dx wrt: 1.single
```

|  | Delta-method |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | dy/dxstd. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |  |
| single <br> Single | .3858462 | .0091398 | 42.22 | 0.000 | .3679324 | .4037599 |

Note: dy/dx for factor levels is the discrete change from the base level.
The average effect of moving each individual from not single to single is an increase in exercise of 0.39 hours, or about 23 minutes.

The statistics $\operatorname{pr}(a, b), \mathrm{e}(a, b)$, and ystar $(a, b)$ produce counterfactual predictions.
These statistics predict what would be observed if the limits $\ell \ell$ and $u \ell$ were the specified $a$ and $b$ and the estimated parameters did not change, even though the parameters of the model were estimated using the limits $\ell \ell$ and $u \ell$.

For example, suppose we model contributions to a retirement plan in a world where the government requires a minimum contribution of $2 \%$ so $\ell \ell=2$. After estimating the model parameters, we could predict the average contribution, given the covariates, when the government raises the minimum contribution to $3 \%$ with the statistic ystar (3,.).

## Methods and formulas

Let $\ell \ell$ refer to the lower limit and $u \ell$ to the upper limit. Also let the probabilities of being at these limits be given by

$$
\begin{aligned}
\operatorname{Pr}\left(y_{i}=\ell \ell \mid \mathbf{z}_{i}\right) & =\Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \gamma_{\ell \ell}\right) \\
\operatorname{Pr}\left(y_{i}=u \ell \mid \mathbf{z}_{i}\right) & =\Phi\left(\mathbf{z}_{i}^{\prime} \gamma_{u \ell}-u \ell\right)
\end{aligned}
$$

where $\mathbf{z}_{i}$ are the covariates of the selection model for individual $i$, which may be distinct from the covariates $\mathbf{x}_{i}$ for the outcome model; $\mathbf{\Phi}$ is the standard normal cumulative distribution function; $\gamma_{\ell \ell}$ is the parameter vector for the lower-limit selection model; and $\gamma_{u \ell}$ is the parameter vector for the upper-limit selection model.

We will limit the exposition below to the case with a lower and an upper limit.
In churdle linear, ystar is equivalent to $E\left(y_{i} \mid \mathbf{x}_{i}\right)$ and is given by

$$
\begin{aligned}
E\left(y_{i} \mid \mathbf{x}_{i}, \mathbf{z}_{i}\right)= & \Phi\left(\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{u \ell}-u \ell\right) u \ell+\Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{\ell \ell}\right) \ell \ell \\
& +\left\{\Phi\left(u \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}\right)-\Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}\right)\right\}\left\{\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}+\sigma \frac{\phi\left(\frac{\ell \ell-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)-\phi\left(\frac{u \ell-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)}{\Phi\left(\frac{u \ell-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)-\Phi\left(\frac{\ell \ell-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)}\right\}
\end{aligned}
$$

$\operatorname{pr}(a, b)$ is given by

$$
\operatorname{Pr}\left(a<y_{i}<b \mid \mathbf{z}_{i}\right)=\Phi\left(b-\mathbf{z}_{i}^{\prime} \boldsymbol{\beta}\right)-\Phi\left(a-\mathbf{z}_{i}^{\prime} \boldsymbol{\beta}\right)
$$

$\mathrm{e}(a, b)$ is given by

$$
E\left(a<y_{i}<b \mid \mathbf{x}_{i}\right)=\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}+\sigma \frac{\phi\left(\frac{a-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)-\phi\left(\frac{b-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)}{\Phi\left(\frac{b-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)-\Phi\left(\frac{a-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right)}
$$

and ystar $(a, b)$ is given by

$$
\begin{aligned}
E\left(y^{*}\right)= & \Phi\left(\mathbf{z}_{i}^{\prime} \gamma_{u \ell}-b\right) b+\Phi\left(a-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{\ell \ell}\right) a \\
& +\operatorname{Pr}\left(a<y_{i}<b \mid \mathbf{x}_{i}\right) E\left(a<y_{i}<b \mid \mathbf{x}_{i}\right)
\end{aligned}
$$

For churdle exponential, ystar is equivalent to

$$
\begin{aligned}
E\left(y_{i} \mid \mathbf{x}_{i}\right)= & \Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{\ell \ell}\right) \ell \ell \\
& +\left\{1-\Phi\left(\ell \ell-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}\right)\right\} \exp \left(\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}+\sigma^{2} / 2\right)\left[\frac{1-\Phi\left\{\frac{\ln (\ell \ell)-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}-\sigma\right\}}{1-\Phi\left\{\frac{\ln (\ell \ell)-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right\}}\right]
\end{aligned}
$$

$\mathrm{p}(a,$.$) is given by$

$$
\operatorname{Pr}\left(a<y_{i} \mid \mathbf{x}_{i}\right)=1-\Phi\left(a-\mathbf{z}_{i}^{\prime} \gamma_{\ell \ell}\right)
$$

$\mathrm{e}(a,$.$) is given by$

$$
E\left(a<y_{i} \mid \mathbf{x}_{i}\right)=\exp \left(\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}+\sigma^{2} / 2\right)\left[\frac{1-\Phi\left\{\frac{\ln (a)-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}-\sigma\right\}}{1-\Phi\left\{\frac{\ln (a)-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}}{\sigma}\right\}}\right]
$$

and ystar $(a,$.$) is given by$

$$
E\left(y^{*}\right)=a \Phi\left(a-\mathbf{z}_{i}^{\prime} \boldsymbol{\gamma}_{\ell \ell}\right)+\operatorname{Pr}\left(a<y_{i} \mid \mathbf{x}_{i}\right) E\left(a<y_{i} \mid \mathbf{x}_{i}\right)
$$

## Title

ci - Confidence intervals for means, proportions, and variances

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| Acknowledgment | References | Also see |  |

## Description

ci computes confidence intervals for population means, proportions, variances, and standard deviations.
cii is the immediate form of ci; see [U] 19 Immediate commands for a general discussion of immediate commands.

## Quick start

Confidence intervals for means of normally distributed variables v1, v2, and v3 ci means v1-v3

Confidence interval for mean of Poisson-distributed variable v4
ci means v4, poisson
Confidence interval for rate of v 4 with total exposure recorded in v 5
ci means v4, poisson exposure(v5)
Confidence interval for proportion of binary variable v6
ci proportions v6
Confidence intervals for variances of $\mathrm{v} 1, \mathrm{v} 2$, and v 3
ci variances v1-v3
Same as above, but Bonett confidence intervals are produced
ci variances v1-v3, bonett
$90 \%$ Bonett confidence intervals for standard deviations of v1, v2, and v3
ci variances v1-v3, sd bonett level(90)
Confidence interval for a mean based on a sample with 85 observations, a sample mean of 10 , and a standard deviation of 3
cii means 85103
$90 \%$ confidence interval for rate from a sample with 4,379 deaths over 11,394 person-years cii means 11394 4379, poisson level(90)

Agresti-Coull confidence interval for proportion based on a sample with 2,377 observations and 136 successes

```
cii proportions 2377 136, agresti
```

Bonett confidence interval for variance based on a sample with 20 observations, sample variance of 9 , and estimated kurtosis of 1.8

```
cii variances 20 9 1.8, bonett
```

Same as above, but with confidence interval for standard deviation cii variances 2031.8 , sd bonett

## Syntax

Confidence intervals for means, normal distribution
ci means $[$ varlist $][$ if $][$ in $][$ weight $][$, options $]$
cii means $\#_{\text {obs }} \#_{\text {mean }} \#_{\text {sd }}[$, level (\#) $]$

Confidence intervals for means, Poisson distribution
ci means [varlist] [if] [in] [weight], poisson [ exposure(varname) options]
cii means $\#_{\text {exposure }} \#_{\text {events }}$, poisson [level(\#)]

Confidence intervals for proportions ci proportions [varlist] [if] [in] [weight] [, prop_options options] cii proportions $\#_{\text {obs }} \#_{\text {succ }}[$, prop_options level(\#)]

Confidence intervals for variances
ci variances [varlist][if][in][weight][, bonett options]
cii variances $\#_{\text {obs }} \#_{\text {variance }}[$, level (\#) $]$
cii variances $\#_{\text {obs }} \#_{\text {variance }} \#_{\text {kurtosis }}$, bonett [level(\#)]

Confidence intervals for standard deviations
ci variances $[$ varlist $][$ if $][$ in $][$ weight], sd [bonett options]
cii variances $\#_{\text {obs }} \#_{\text {sd }}$, sd [level(\#)]
cii variances $\#_{\text {obs }} \#_{\text {sd }} \#_{\text {kurtosis }}$, sd bonett [ level (\#) $]$
$\#_{\text {obs }}$ must be a positive integer. \#exposure, $\#_{\text {sd }}$, and $\#_{\text {variance }}$ must be a positive number. \# succ and $\#_{\text {events }}$ must be a nonnegative integer or between 0 and 1 . If the number is between 0 and 1 , Stata interprets it as the fraction of successes or events and converts it to an integer number representing the number of successes or events. The computation then proceeds as if two integers had been specified. If option bonett is specified, you must additionally specify $\#_{\text {kurtosis }}$ with cii variances.
exact
wald
wilson
agresti
jeffreys
calculate exact confidence intervals; the default calculate Wald confidence intervals calculate Wilson confidence intervals calculate Agresti-Coull confidence intervals calculate Jeffreys confidence intervals

## options

Description
level(\#)
separator(\#)
total
set confidence level; default is level (95)
draw separator line after every \# variables; default is separator (5) add output for all groups combined (for use with by only)
by, collect, and statsby are allowed with ci, and collect is allowed with cii; see [U] 11.1.10 Prefix commands. aweights are allowed with ci means for normal data, and fweights are allowed with all ci subcommands; see
[U] 11.1.6 weight.

## Options

Options are presented under the following headings:
Options for ci and cii means
Options for ci and cii proportions
Options for ci and cii variances

## Options for ci and cii means

$\qquad$ Main
poisson specifies that the variables (or numbers for cii) are Poisson-distributed counts; exact Poisson confidence intervals will be calculated. By default, confidence intervals for means are calculated based on a normal distribution.
exposure (varname) is used only with poisson. You do not need to specify poisson if you specify exposure(); poisson is assumed. varname contains the total exposure (typically a time or an area) during which the number of events recorded in varlist was observed.
level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [R] level.
separator(\#) specifies how often separation lines should be inserted into the output. The default is separator (5), meaning that a line is drawn after every five variables. separator (10) would draw the line after every 10 variables. separator ( 0 ) suppresses the separation line.
total is used with the by prefix. It requests that in addition to output for each by-group, output be added for all groups combined.

## Options for ci and cii proportions

$\qquad$
exact, wald, wilson, agresti, and jeffreys specify how binomial confidence intervals are to be calculated.
exact is the default and specifies exact (also known in the literature as Clopper-Pearson [1934]) binomial confidence intervals.
wald specifies calculation of Wald confidence intervals.
wilson specifies calculation of Wilson confidence intervals.
agresti specifies calculation of Agresti-Coull confidence intervals.
jeffreys specifies calculation of Jeffreys confidence intervals.
See Brown, Cai, and DasGupta (2001) for a discussion and comparison of the different binomial confidence intervals.
level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [R] level.
separator (\#) specifies how often separation lines should be inserted into the output. The default is separator (5), meaning that a line is drawn after every five variables. separator (10) would draw the line after every 10 variables. separator ( 0 ) suppresses the separation line.
total is used with the by prefix. It requests that in addition to output for each by-group, output be added for all groups combined.

## Options for ci and cii variances

$\qquad$ Main
sd specifies that confidence intervals for standard deviations be calculated. The default is to compute confidence intervals for variances.
bonett specifies that Bonett confidence intervals be calculated. The default is to compute normal-based confidence intervals, which assume normality for the data.
level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [R] level.
separator (\#) specifies how often separation lines should be inserted into the output. The default is separator (5), meaning that a line is drawn after every five variables. separator (10) would draw the line after every 10 variables. separator ( 0 ) suppresses the separation line.
total is used with the by prefix. It requests that in addition to output for each by-group, output be added for all groups combined.

## Remarks and examples

Remarks are presented under the following headings:
Confidence intervals for means Normal-based confidence intervals
Poisson confidence intervals
Confidence intervals for proportions
Confidence intervals for variances
Immediate form

## Confidence intervals for means

ci means computes a confidence interval for the population mean for each of the variables in varlist.

## Normal-based confidence intervals

## > Example 1: Normal-based confidence intervals

Without the poisson option, ci means produces normal-based confidence intervals that are correct if the variable is normally distributed and asymptotically correct for all other distributions satisfying the conditions of the central limit theorem.

```
. use https://www.stata-press.com/data/r18/auto
```

(1978 automobile data)
. ci means mpg price

| Variable | Obs | Mean | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| mpg | 74 | 21.2973 | .6725511 | 19.9569 | 22.63769 |
| price | 74 | 6165.257 | 342.8719 | 5481.914 | 6848.6 |

The standard error of the mean of mpg is 0.67 , and the $95 \%$ confidence interval is [19.96, 22.64]. We can obtain wider confidence intervals, $99 \%$, by typing
. ci means mpg price, level(99)

| Variable | Obs | Mean | Std. err. | [99\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| mpg | 74 | 21.2973 | .6725511 | 19.51849 | 23.07611 |
| price | 74 | 6165.257 | 342.8719 | 5258.405 | 7072.108 |

## > Example 2: The by prefix

The by prefix breaks out the confidence intervals according to by-group; total adds an overall summary. For instance,
. by foreign: ci means mpg, total

| Variable | Obs | Mean | Std. err. | [95\% conf | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: |
| mpg | 52 | 19.82692 | . 657777 | 18.50638 | 21.14747 |
| -> foreign = Foreign |  |  |  |  |  |
| Variable | Obs | Mean | Std. err. | [95\% conf | interval] |
| mpg | 22 | 24.77273 | 1.40951 | 21.84149 | 27.70396 |
| -> Total |  |  |  |  |  |
| Variable | Obs | Mean | Std. err. | [95\% conf | interval] |
| mpg | 74 | 21.2973 | . 6725511 | 19.9569 | 22.63769 |

> Example 3: Controlling the format
You can control the formatting of the numbers in the output by specifying a display format for the variable; see [U] 12.5 Formats: Controlling how data are displayed. For instance,
. format mpg \%9.2f

| ci means mpg |
| ---: | ---: | ---: | ---: | ---: | ---: |
| Variable |

mpg

## Poisson confidence intervals

If you specify the poisson option, ci means assumes count data and computes exact Poisson confidence intervals.
> Example 4: Poisson confidence intervals
We have data on the number of bacterial colonies on a Petri dish. The dish has been divided into 36 small squares, and the number of colonies in each square has been counted. Each observation in our dataset represents a square on the dish. The variable count records the number of colonies in each square counted, which varies from 0 to 5 .

```
. use https://www.stata-press.com/data/r18/petri, clear
. ci means count, poisson
```

| Variable | Exposure | Mean | Std. err. | Poisson exact <br> [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| count | 36 | 2.333333 | .2545875 | 1.861158 | 2.888825 |

ci reports that the average number of colonies per square is 2.33 . If the expected number of colonies per square were as low as 1.86 , the probability of observing 2.33 or more colonies per square would be $2.5 \%$. If the expected number were as large as 2.89 , the probability of observing 2.33 or fewer colonies per square would be $2.5 \%$.

## > Example 5: Option exposure()

The number of "observations"-how finely the Petri dish is divided-makes no difference. The Poisson distribution is a function only of the count. In example 4, we observed a total of $2.33 \times 36=84$ colonies and a confidence interval of $[1.86 \times 36,2.89 \times 36]=[67,104]$. We would obtain the same $[67,104]$ confidence interval if our dish were divided into, say, 49 squares rather than 36.

For the counts, it is not even important that all the squares be of the same size. For rates, however, such differences do matter but in an easy-to-calculate way. Rates are obtained from counts by dividing by exposure, which is typically a number multiplied by either time or an area. For our Petri dishes, we divide by an area to obtain a rate, but if our example were cast in terms of being infected by a disease, we might divide by person-years to obtain the rate. Rates are convenient because they are easier to compare: we might have 2.3 colonies per square inch or 0.0005 infections per person-year.

So let's assume that we wish to obtain the number of colonies per square inch and, moreover, that not all the "squares" on our dish are of equal size. We have a variable called area that records the area of each square:

```
. ci means count, exposure(area)
```

| Variable | Exposure | Mean | Std. err. | Poisson exact <br> [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| count | 3 | 28 | 3.055051 | 22.3339 | 34.66591 |

The rates are now in more familiar terms. In our sample, there are 28 colonies per square inch, and the $95 \%$ confidence interval is [22.3, 34.7]. When we did not specify exposure(), ci means with option poisson assumed that each observation contributed 1 to exposure.

- Technical note

If there were no colonies on our dish, ci means with option poisson would calculate a one-sided confidence interval:
. use https://www.stata-press.com/data/r18/petrinone
. ci means count, poisson

| Variable | Exposure | Mean | Std. err. | Poisson exact <br> [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| count | 36 | 0 | 0 | 0 | $.1024689 *$ |

(*) one-sided, $97.5 \%$ confidence interval

## Confidence intervals for proportions

The ci proportions command assumes binary ( $0 / 1$ ) data and computes binomial confidence intervals.
> Example 6: Exact binomial (Clopper-Pearson) confidence interval
We have data on employees, including a variable marking whether the employee was promoted last year.
. use https://www.stata-press.com/data/r18/promo
. ci proportions promoted

| Variable | Obs Proportion | Std. err. | Binomial exact <br> [95\% conf. interval] |  |  |
| :---: | ---: | :---: | :---: | :---: | ---: |
| promoted | 20 | .1 | .067082 | .0123485 | .3169827 |

The exact binomial, also known as the Clopper-Pearson (1934) interval, is computed by default.
Nominally, the interpretation of a $95 \%$ confidence interval is that under repeated samples or experiments, $95 \%$ of the resultant intervals would contain the unknown parameter in question. However, for binomial data, the actual coverage probability, regardless of method, usually differs from that interpretation. This result occurs because of the discreteness of the binomial distribution, which produces only a finite set of outcomes, meaning that coverage probabilities are subject to discrete jumps and that the exact nominal level cannot always be achieved. Therefore, the term "exact confidence interval" refers to its being derived from the binomial distribution, the distribution exactly generating the data, rather than resulting in exactly the nominal coverage.

For the Clopper-Pearson interval, the actual coverage probability is guaranteed to be greater than or equal to the nominal confidence level, here $95 \%$. Because of the way it is calculated-see Methods and formulas-it may also be interpreted as follows: If the true probability of being promoted were 0.012 , the chances of observing a result as extreme or more extreme than the result observed ( $20 \times 0.1=2$ or more promotions) would be $2.5 \%$. If the true probability of being promoted were 0.317 , the chances of observing a result as extreme or more extreme than the result observed (two or fewer promotions) would be $2.5 \%$.

## > Example 7: Other confidence intervals

The Clopper-Pearson interval is desirable because it guarantees nominal coverage; however, by dropping this restriction, you may obtain accurate intervals that are not as conservative. In this vein, you might opt for the Wilson (1927) interval,
. ci proportions promoted, wilson

| Variable | Obs Proportion | Std. err. | Wilson |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| [95\% conf. interval] |  |  |  |  |  |
| promoted | 20 | .1 | .067082 | .0278665 | .3010336 |

the Agresti-Coull (1998) interval,
. ci proportions promoted, agresti

| Variable | Obs | Proportion | Std. err. | Agresti-Coull <br> [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| promoted | 20 | .1 | .067082 | .0156562 | .3132439 |

or the Bayesian-derived Jeffreys interval (Brown, Cai, and DasGupta 2001),
. ci proportions promoted, jeffreys

| Variable | Obs | Jroportion |  | Std. err. | [95\% conf. interval] |
| :---: | ---: | :---: | :---: | ---: | ---: |
| promoted | 20 | .1 | .067082 | .0213725 | .2838533 |

Picking the best interval is a matter of balancing accuracy (coverage) against precision (average interval length) and depends on sample size and success probability. Brown, Cai, and DasGupta (2001) recommend the Wilson or Jeffreys interval for small sample sizes $(\leq 40)$ yet favor the Agresti-Coull interval for its simplicity, decent performance for sample sizes less than or equal to 40 , and performance comparable to Wilson or Jeffreys for sample sizes greater than 40 . They also deem the ClopperPearson interval to be "wastefully conservative and [...] not a good choice for practical use", unless of course one requires, at a minimum, the nominal coverage level.

Finally, the binomial Wald confidence interval is obtained by specifying the wald option. The Wald interval is the one taught in most introductory statistics courses and, for the above, is simply, for level $1-\alpha$, Proportion $\pm z_{\alpha / 2}$ (Std. err.), where $z_{\alpha / 2}$ is the $1-\alpha / 2$ quantile of the standard normal. Because its overall poor performance makes it impractical, the Wald interval is available mainly for pedagogical purposes. The binomial Wald interval is also similar to the interval produced by treating binary data as normal data and using ci means, with two exceptions. First, the calculation of the standard error in ci proportions uses denominator $n$ rather than $n-1$, used for normal data in ci means. Second, confidence intervals for normal data are based on the $t$ distribution rather than the standard normal. Of course, both discrepancies vanish as sample size increases.

- Technical note

Let's repeat example 6, but this time with data in which there are no promotions over the observed period:

```
. use https://www.stata-press.com/data/r18/promonone
. ci proportions promoted
```

| Variable | Obs Proportion | Std. err. | Binomial exact <br> [95\% conf. interval] |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| promoted | 20 | 0 | 0 | 0 | $.1684335 *$ |
| (*) one-sided, $97.5 \%$ confidence interval |  |  |  |  |  |

The confidence interval is $[0,0.168]$, and this is the confidence interval that most books publish. It is not, however, a true $95 \%$ confidence interval because the lower tail has vanished. As Stata notes, it is a one-sided, $97.5 \%$ confidence interval. If you wanted to put $5 \%$ in the right tail, you could type ci proportions promoted, level(90).

## - Technical note

ci proportions ignores any variables that do not take on the values 0 and 1 exclusively. For instance, with our automobile dataset,

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. ci proportions mpg foreign
\begin{tabular}{c|ccccc} 
Variable & Obs & & \multicolumn{2}{c}{\begin{tabular}{c} 
Binomial exact \\
[95\% conf. interval]
\end{tabular}} \\
\hline foreign & 74 & .2972973 & .0531331 & .196584 & .4148353 \\
Note: The results are produced only for binary (0/1) & variables.
\end{tabular}
Note: The results are produced only for binary (0/1) variables.
```

We also requested the confidence interval for mpg , but Stata ignored us. It does that so you can type ci proportions and obtain correct confidence intervals for all the variables that are $0 / 1$ in your data.

## Confidence intervals for variances

The ci variances command computes confidence intervals for the variances or, if the sd option is specified, for the standard deviations. The default is a normal-based confidence interval that assumes the data are normal and uses a $\chi^{2}$ distribution to construct the confidence intervals. If normality is suspect, you may consider using the bonett option to compute Bonett (2006) confidence intervals, which are more robust to nonnormality.
> Example 8: Normal-based confidence intervals
So far, we have restricted our attention to confidence intervals for means and proportions. Typically, when people think of statistical inference, they usually have in mind inferences concerning population means. However, the population parameter of interest will vary from one situation to another. In many scenarios, the population variance is as important as the population mean. For example, in a quality
control study, a machine that fills 16 -ounce canned peas is investigated at regular time intervals. A random sample of $n=8$ containers is selected every hour. Ideally, the amount of peas in a can should vary only slightly about the 16 -ounce value. If the variance was large, then a large proportion of cans would be either underfilled, thus cheating the customer, or overfilled, thus resulting in economic loss to the manufacturing company. Suppose that the weights of 16 -ounce cans filled by the machine are normally distributed. The acceptable variability in the weights is expected to be 0.09 with the respective standard deviation of 0.3 ounces. To monitor the machine's performance, we can compute confidence intervals for the variance of the weights of cans:

| . use https://www.stata-press.com/data/r18/peas_normdist <br> (Weights of canned peas, normal distribution) |
| :--- |
| . ci variances weight <br> Variable |
| weight |

The command reports the sample estimate of the variance of 0.39 with the $95 \%$ confidence interval of $[0.17,1.61]$.

Instead of the variance, we may be interested in confidence intervals for the standard deviation. We can specify the sd option to compute such confidence intervals.

```
. ci variances weight, sd
```

| Variable | Obs | Std. dev. | [95\% conf. interval] |  |
| ---: | ---: | :---: | ---: | :---: |
| weight | 8 | .6235711 | .4122891 | 1.269137 |

The $95 \%$ confidence interval for the standard deviation of the weights is [0.41, 1.27]. Because the desired value for the standard deviation, 0.3 ounces, falls outside the interval, the machine may require some tuning.

Confidence intervals in example 8 are based on the assumption that the random sample is selected from a population having a normal distribution. Nonnormality of the population distribution, in the form of skewness or heavy tails, can have a drastic impact on the asymptotic coverage probability of the normal-based confidence intervals. This is the case even for distributions that are similar to normal. Scheffé $(1959,336)$ showed that the normal-based interval has an asymptotic coverage probability of about $0.76,0.63,0.60$, and 0.51 for the logistic, $t$ with seven degrees of freedom, Laplace, and $t$ with five degrees of freedom distributions, respectively. Miller $(1997,264)$ describes this situation as "catastrophic" because these distributions are symmetric and not easily distinguishable from a normal distribution unless the sample size is large. Hence, it is judicious to evaluate the normality of the data prior to constructing the normal-based confidence intervals for variances or standard deviations.

Bonett (2006) proposed a confidence interval that performs well in small samples under moderate departures from normality. His interval performs only slightly worse than the exact normal-based confidence interval when sampling from a normal distribution. A larger sample size provides Bonett confidence intervals with greater protection against nonnormality.

## > Example 9: Bonett confidence interval for normal data

We will repeat example 8 and construct a Bonett confidence interval for the standard deviation by specifying the bonett option. The results are similar, and both examples lead to the same inferential conclusion.
. ci variances weight, sd bonett

| Variable | Obs | Std. dev. | [95\% conf. interval] |  |
| ---: | :---: | :---: | :---: | :---: |
| weight | 8 | .6235711 | .3997041 | 1.288498 |

The Bonett confidence interval is wider than the normal-based confidence interval in example 8. For normal data, Bonett (2006) suggested that if Bonett confidence interval is used for a sample of size $n+3$, then its average width will be about the same as the average width of the normal-based confidence interval from a sample size of $n$. Sampling three more observations may be a small price to pay because Bonett confidence intervals perform substantially better than the normal-based confidence intervals for nonnormal data.

## > Example 10: Bonett confidence interval for nonnormal data

The following data have been generated from a $t$ distribution with five degrees of freedom to illustrate the effect of wrongfully using the normal-based confidence interval when the data-generating process is not normal.
. use https://www.stata-press.com/data/r18/peas_tdist

| (Weights of canned peas, t distribution) |
| :--- |
| - ci variances weight, sd |
| Variable |$\quad$| Obs | Std. dev. | [95\% conf. interval] |  |  |
| ---: | :--- | :--- | :--- | :--- |
| weight | 8 | 2.226558 | 1.472143 | 4.531652 |

The standard deviation of a $t$ distribution with five degrees of freedom is $\sqrt{5 / 3} \approx 1.29$ and falls outside the confidence interval limits. If we suspect that data may not be normal, the Bonett confidence interval is typically a better choice:
. ci variances weight, sd bonett

| Variable | Obs | Std. dev. | Bonett |  |
| ---: | ---: | :--- | :--- | :--- |
| [95\% conf. interval] |  |  |  |  |

The value 1.29 is within the limits of the Bonett confidence interval [1.14, 5.77]

## Immediate form

So far, we computed confidence intervals for various parameters using data in memory. We can also compute confidence intervals using only data summaries, without any data in memory. Each of the considered ci commands has an immediate cii version that computes the respective confidence intervals using data summaries.

## > Example 11: Confidence interval for a normal mean

We are reading a soon-to-be-published paper by a colleague. In it is a table showing the number of observations, mean, and standard deviation of the 1980 median family income for the Northeast and West. We correctly think that the paper would be much improved if it included the confidence intervals. The paper claims that for 166 cities in the Northeast, the average of median family income is $\$ 19,509$ with a standard deviation of $\$ 4,379$ :

For the Northeast:

```
. cii means 166 19509 4379
```

| Variable | Obs | Mean | Std. err. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 166 | 19509 | 339.8763 | 18837.93 | 20180.07 |

For the West:

| cii means 256 <br> Variable | Obs |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 25003 | Mean | Std. err. | [95\% conf. interval] |  |
|  | 256 | 22557 | 312.6875 | 21941.22 | 23172.78 |

> Example 12: Confidence interval for a Poisson mean
The number of reported traffic accidents in Santa Monica over a 24 -hour period is 27 . We need know nothing else to compute a confidence interval for the mean number of accidents for a day:

```
. cii means 1 27, poisson
```

| Variable | Exposure | Mean | Std. err. | Poisson exact <br> [95\% conf. interval] |  |
| :---: | ---: | :---: | :---: | :---: | :---: |
|  | 1 | 27 | 5.196152 | 17.79317 | 39.28358 |

## > Example 13: Confidence interval for a proportion

We flip a coin 10 times, and it comes up heads only once. We are shocked and decide to obtain a $99 \%$ confidence interval for this coin:
. cii proportions 10 1, level(99)

| Variable | Obs |  | Binomial exact <br> [99\% conf. interval] |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 10 | .1 | .0948683 | .0005011 | .5442871 |

## > Example 14: Confidence interval for a variance

A company fills 32-ounce tomato juice jars with a quantity of juice having a normal distribution with a claimed variance not exceeding 0.2 . A random sample of 15 jars is collected to evaluate this claim. The sample variance is 0.5 :
. cii variances 150.5

| Variable | Obs | Variance | [95\% conf. interval] |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 15 | .5 | .2680047 | 1.243621 |  |

Because the advertised value of 0.2 does not fall inside the confidence interval, the company is allowing too much variation in the amount of tomato juice per jar.
> Example 15: Confidence interval for a standard deviation
Suppose the director of statistical development at a statistical software company is a big soccer fan and requires all developers to play on the company team in the city's local soccer league. Ten developers are randomly selected to participate in the game. To ensure an advantage over other teams, the director requires each of the 10 developers to cover 6 miles on average each game. Being merciful, she will tolerate a standard deviation of 0.3 miles across different players, arguing that this will keep the team's performance consistent. The distance covered by each player is measured using a pedometer. At the end of the game, the sample standard deviation of the distances covered by the 10 players was 0.56 miles:

```
. cii variances 10 0.56, sd
```

| Variable | Obs | Std. dev. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: |
|  | 10 | .56 | .3851877 | 1.022342 |

Because the confidence interval does not include the designated value for the standard deviation, 0.3 miles, it is clear the team is not meeting standards, and an unpleasant meeting is planned.

## > Example 16: Confidence interval for a standard deviation of nonnormal data

Continuing with example 15, a clever statistician points out that distances covered by company players in a soccer match do not follow the normal distribution because some players, mostly econometricians, walk on the field, while others, mostly statisticians, do all the running. Therefore, the normal-based confidence interval (which assumes normality) is not valid. Instead, we should use the Bonett confidence interval, which additionally requires an estimate of kurtosis; see Methods and formulas. If kurtosis is estimated to be 5, we would obtain the following:

```
. cii variances 10 0.56 5, sd bonett
```

| Variable | Obs | Std. dev. | Bonett |  |
| :---: | :---: | :---: | :---: | :---: |
|  | [95\% conf. interval] |  |  |  |
|  | 10 | .56 | .2689449 | 1.45029 |

The Bonett confidence interval now contains the specified value for the standard deviation, 0.3 miles. The director of statistics concludes that overall team performance is acceptable. An uncomfortable meeting is still planned but for a smaller group.

## Stored results

ci means and cii means store the following in r() :
Scalars
$r(N) \quad$ number of observations or, if poisson is specified, exposure
$r$ (mean)
$r$ (se)
r(lb)
$r(u b)$
r(level) mean
estimate of standard error
lower bound of confidence interval
upper bound of confidence interval
confidence level of confidence interval
Macros
$r$ (citype) normal or poisson; type of confidence interval
r(exposure)
ci proportions and cii proportions store the following in $r()$ :

Scalars
$r(N)$
$r$ (proportion)
$r(\mathrm{se})$
r(lb)
$r(u b)$
$r$ (level)
Macros
r(citype)
number of observations
proportion
estimate of standard error
lower bound of confidence interval upper bound of confidence interval confidence level of confidence interval
exact, wald, wilson, agresti, or jeffreys; type of confidence interval
ci variances and cii variances store the following in $r()$ :
Scalars
$r(N) \quad$ number of observations
$r$ (Var) variance
$r$ (sd) standard deviation, if sd is specified
$r$ (kurtosis) kurtosis, only if bonett is specified
$r(l b) \quad$ lower bound of confidence interval
$r$ (ub)
$r$ (level) upper bound of confidence interval confidence level of confidence interval
Macros
r(citype) normal or bonett, type of confidence interval

## Methods and formulas

Methods and formulas are presented under the following headings:
Normal mean
Poisson mean
Binomial proportion
Variance and standard deviation

## Normal mean

Define $n, \bar{x}$, and $s^{2}$ as, respectively, the number of observations, (weighted) average, and (unbiased) estimated variance of the variable in question; see $[R]$ summarize.

The standard error of the mean, $s_{\mu}$, is defined as $\sqrt{s^{2} / n}$.
Let $\alpha$ be $1-l / 100$, where $l$ is the confidence level specified by the user in the level() option. Define $t_{\alpha / 2}$ as the two-sided $t$ statistic corresponding to a significance level of $\alpha$ with $n-1$ degrees of freedom; $t_{\alpha / 2}$ is obtained from Stata as invttail ( $n-1,0.5 * \alpha$ ). The lower and upper confidence bounds are, respectively, $\bar{x}-s_{\mu} t_{\alpha / 2}$ and $\bar{x}+s_{\mu} t_{\alpha / 2}$.

## Poisson mean

Given the total cases, $k$, the estimate of the expected count $\lambda$ is $k$, and its standard error is $\sqrt{k}$. ci means with option poisson calculates the exact confidence interval [ $\lambda_{1}, \lambda_{2}$ ] such that

$$
\operatorname{Pr}\left(K \geq k \mid \lambda=\lambda_{1}\right)=\alpha / 2
$$

and

$$
\operatorname{Pr}\left(K \leq k \mid \lambda=\lambda_{2}\right)=\alpha / 2
$$

where $K$ is Poisson with mean $\lambda$. Solution is obtained by Newton's method. If $k=0$, the calculation of $\lambda_{1}$ is skipped. All values are then reported as rates, which are the above numbers divided by the total exposure.

## Binomial proportion

Given $k$ successes of $n$ trials, the estimated probability of a success is $\widehat{p}=k / n$ with standard error $\sqrt{\widehat{p}(1-\widehat{p}) / n}$. ci calculates the exact (Clopper-Pearson) confidence interval $\left[p_{1}, p_{2}\right]$ such that

$$
\operatorname{Pr}\left(K \geq k \mid p=p_{1}\right)=\alpha / 2
$$

and

$$
\operatorname{Pr}\left(K \leq k \mid p=p_{2}\right)=\alpha / 2
$$

where $K$ is distributed as $\operatorname{binomial}(n, p)$. The endpoints may be obtained directly by using Stata's invbinomial() function. If $k=0$ or $k=n$, the calculation of the appropriate tail is skipped.

The Wald interval is $\widehat{p} \pm z_{\alpha / 2} \sqrt{\widehat{p}(1-\widehat{p}) / n}$, where $z_{\alpha / 2}$ is the $1-\alpha / 2$ quantile of the standard normal. The interval is obtained by inverting the acceptance region of the large-sample Wald test of $H_{0}: p=p_{0}$ versus the two-sided alternative. That is, the confidence interval is the set of all $p_{0}$ such that

$$
\left|\frac{\widehat{p}-p_{0}}{\sqrt{n^{-1} \widehat{p}(1-\widehat{p})}}\right| \leq z_{\alpha / 2}
$$

The Wilson interval is a variation on the Wald interval, using the null standard error $\sqrt{n^{-1} p_{0}\left(1-p_{0}\right)}$ in place of the estimated standard error $\sqrt{n^{-1} \widehat{p}(1-\widehat{p})}$ in the above expression. Inverting this acceptance region is more complicated yet results in the closed form

$$
\frac{k+z_{\alpha / 2}^{2} / 2}{n+z_{\alpha / 2}^{2}} \pm \frac{z_{\alpha / 2} n^{1 / 2}}{n+z_{\alpha / 2}^{2}}\left\{\widehat{p}(1-\widehat{p})+\frac{z_{\alpha / 2}^{2}}{4 n}\right\}^{1 / 2}
$$

The Agresti-Coull interval is basically a Wald interval that borrows its center from the Wilson interval. Defining $\widetilde{k}=k+z_{\alpha / 2}^{2} / 2, \widetilde{n}=n+z_{\alpha / 2}^{2}$, and (hence) $\widetilde{p}=\widetilde{k} / \widetilde{n}$, the Agresti-Coull interval is

$$
\widetilde{p} \pm z_{\alpha / 2} \sqrt{\widetilde{p}(1-\widetilde{p}) / \widetilde{n}}
$$

When $\alpha=0.05, z_{\alpha / 2}$ is near enough to 2 that $\widetilde{p}$ can be thought of as a typical estimate of proportion where two successes and two failures have been added to the sample (Agresti and Coull 1998). This typical estimate of proportion makes the Agresti-Coull interval an easy-to-present alternative for introductory statistics students.

The Jeffreys interval is a Bayesian credible interval and is based on the Jeffreys prior, which is the $\operatorname{Beta}(1 / 2,1 / 2)$ distribution. Assigning this prior to $p$ results in a posterior distribution for $p$ that is Beta with parameters $k+1 / 2$ and $n-k+1 / 2$. The Jeffreys interval is then taken to be the $1-\alpha$ central posterior probability interval, namely, the $\alpha / 2$ and $1-\alpha / 2$ quantiles of the $\operatorname{Beta}(k+1 / 2, n-k+1 / 2)$ distribution. These quantiles may be obtained directly by using Stata's invibeta() function. See [BAYES] bayesstats summary for more details about credible intervals.

## Variance and standard deviation

Let $X_{1}, \ldots, X_{n}$ be a random sample and assume that $X_{i} \sim N\left(\mu, \sigma^{2}\right)$. Because $(n-1) s^{2} / \sigma^{2} \sim$ $\chi_{n-1}^{2}$, we have $\operatorname{Pr}\left\{\chi_{n-1, \alpha / 2}^{2} \leq(n-1) s^{2} / \sigma^{2} \leq \chi_{n-1,1-\alpha / 2}^{2}\right\}=1-\alpha$, where $\chi_{n-1, \alpha / 2}^{2}$ and $\chi_{n-1,1-\alpha / 2}^{2}$ are the $\alpha / 2$ and $1-\alpha / 2$ quantiles of the $\chi_{n-1}^{2}$ distribution. Thus, the normal-based confidence interval for the population variance $\sigma^{2}$ with $100(1-\alpha) \%$ confidence level is given by

$$
I_{\text {normal }}=\left[\frac{(n-1) s^{2}}{\chi_{n-1,1-\alpha / 2}^{2}}, \frac{(n-1) s^{2}}{\chi_{n-1, \alpha / 2}^{2}}\right]
$$

$\chi_{n-1,1-\alpha / 2}^{2}$ and $\chi_{n-1, \alpha / 2}^{2}$ are obtained from Stata as invchi2tail ( $n-1,0.5 * \alpha$ ) and invchi2( $n-$ $1,0.5 * \alpha)$, respectively.

The normal-based confidence interval is very sensitive to minor departures from the normality assumption, and its performance does not improve with increasing sample size. For scenarios in which the population distribution is not normal, the actual coverage probability of the normal-based confidence interval can be drastically lower than the nominal confidence level $\alpha$.

Bonett (2006) proposed an alternative to the normal-based confidence interval that is nearly exact under normality and has coverage probability close to $1-\alpha$ under moderate nonnormality. It also has $1-\alpha$ asymptotic coverage probability for nonnormal distributions with finite fourth moment. Instead of assuming that $X_{i} \sim N\left(\mu, \sigma^{2}\right)$, Bonett's approach requires continuous i.i.d. random variables with finite fourth moment. The variance of $s^{2}$ may be expressed as $\sigma^{4}\left\{\gamma_{4}-(n-3) /(n-1)\right\} / n$ (see Casella and Berger [2002, ex. 5.8, 257]), where $\gamma_{4}=\mu^{4} / \sigma^{4}$ is the kurtosis and $\mu^{4}=E\left(X_{i}-\mu\right)^{4}$ is the population fourth central moment. The variance-stabilizing transformation $\ln \left(s^{2}\right)$ and the delta method can be used to construct an asymptotic $100(1-\alpha) \%$ confidence interval for $\sigma^{2}$,

$$
\left[\exp \left\{\ln \left(s^{2}\right)-z_{\alpha / 2} s e\right\}, \exp \left\{\ln \left(s^{2}\right)+z_{\alpha / 2} s e\right\}\right]
$$

where se $=\left\{\widehat{\gamma}_{4}-(n-3) /(n-1)\right\} / n \approx \operatorname{Var}\left\{\ln \left(s^{2}\right)\right\}$ and $\widehat{\gamma}_{4}$ is an estimate of the kurtosis. Bonett introduced three adjustments to improve the small-sample properties of the above confidence interval. First, he swapped the inner and outer denominator in the expression for se and changed it to $\left\{\widehat{\gamma}_{4}-(n-3) / n\right\} /(n-1)$. This was suggested by Shoemaker (2003) who used it to improve the small-sample performance of his variance test. Second, with regard to the estimation of kurtosis, Bonett proposed $\widehat{\gamma}_{4}=n \sum\left(X_{i}-m\right)^{4} /\left\{\sum\left(X_{i}-\bar{X}\right)^{2}\right\}^{2}$, where $m$ is a trimmed mean with a trimproportion equal to $1 /\left\{2(n-4)^{1 / 2}\right\}$. This kurtosis estimator reduces the negative bias in symmetric and skewed heavy-tailed distributions. Last, he empirically derived a small-sample correction factor $c=n /\left(n-z_{\alpha / 2}\right)$ that helps equalize the tail probabilities. These modifications yield

$$
I_{\text {Bonett }}=\left[\exp \left\{\ln \left(c s^{2}\right)-z_{\alpha / 2} s e\right\}, \exp \left\{\ln \left(c s^{2}\right)+z_{\alpha / 2} s e\right\}\right]
$$

where $z_{\alpha / 2}$ is the $1-\alpha / 2$ quantile of the standard normal and se $=c\left[\left\{\widehat{\gamma}_{4}-(n-3) / n\right\} /(n-1)\right]$.
Taking the square root of the endpoints of both intervals gives confidence intervals for the standard deviation $\sigma$.

Edwin Bidwell (E. B.) Wilson (1879-1964) majored in mathematics at Harvard and studied and taught at Yale and mit before returning to Harvard in 1922. He worked in mathematics, physics, and statistics. His method for binomial intervals can be considered a precursor, for a particular problem, of Neyman's concept of confidence intervals.
Jerzy Neyman (1894-1981) was born in Bendery, Russia, now Moldavia. He studied and then taught at Kharkov University, moving from physics to mathematics. In 1921, Neyman moved to Poland, where he worked in statistics at Bydgoszcz and then Warsaw. Neyman received a Rockefeller Fellowship to work with Karl Pearson at University College London. There he collaborated with Egon Pearson, Karl's son, on the theory of hypothesis testing. Life in Poland became progressively more difficult, and Neyman returned to UCL to work there from 1934 to 1938. At this time, he published on the theory of confidence intervals. He then was offered a post in California at Berkeley, where he settled. Neyman established an outstanding statistics department and remained highly active in research, including applications in astronomy, meteorology, and medicine. He was one of the great statisticians of the 20th century.

## Acknowledgment

We thank Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the Stata Journal and author of Speaking Stata Graphics for his assistance with the jeffreys and wilson options.

## Title

clogit — Conditional (fixed-effects) logistic regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

clogit fits a conditional logistic regression model for matched case-control data, also known as a fixed-effects logit model for panel data. clogit can compute robust and cluster-robust standard errors and adjust results for complex survey designs.

See [CM] cmclogit if you want to fit McFadden's choice model (McFadden 1974).

## Quick start

Conditional logistic regression model of y on x with matched case-control pairs data identified by idvar

```
clogit y x, group(idvar)
```

Fixed-effects logistic regression model with panels identified by idvar
clogit y x, group(idvar)
Add categorical variable a and report results as odds ratios
clogit y x i.a, group(idvar) or
Same as above, but using sampling probability weight wvar
clogit y x i.a [pweight = wvar], group(idvar) or

## Menu

Statistics $>$ Binary outcomes $>$ Conditional logistic regression

## Syntax

clogit depvar [indepvars] [if] [in] [weight], group(varname) [options]
depvar is treated as binary regardless of values; depvar equal to nonzero and nonmissing (typically equal to 1) indicates a positive outcome, whereas depvar equal to 0 indicates a negative outcome.

## options

Description
Model

* group (varname)
offset (varname)
constraints (constraints)
matched group variable
include varname in model with coefficient constrained to 1
apply specified linear constraints
SE/Robust
vce(vcetype)
nonest
vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife
do not check that panels are nested within clusters
Reporting
level(\#)
or
nocnsreport
display_options
set confidence level; default is level (95)
report odds ratios
do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

Maximization
maximize_options
collinear
coeflegend
control the maximization process; seldom used
keep collinear variables
display legend instead of statistics

* group (varname) is required.
indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
bayes, bootstrap, by, collect, fp, jackknife, mfp, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: clogit.
vce (bootstrap) and vce (jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
vce(), nonest, and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed (see [U] 11.1.6 weight), but they are interpreted to apply to groups as a whole, not to individual observations. See Use of weights below.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

## Model

group (varname) is required; it specifies an identifier variable (numeric or string) for the matched groups. strata(varname) is a synonym for group().
offset (varname), constraints (constraints); see [R] Estimation options.
vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
nonest, available only with vce(cluster clustvar), prevents checking that matched groups are nested within clusters. It is the user's responsibility to verify that the standard errors are theoretically correct.

Reporting
level (\#); see [R] Estimation options.
or reports the estimated coefficients transformed to odds ratios, that is, $e^{b}$ rather than $b$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.
nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% $\% m t$ ), and nolstretch; see [R] Estimation options.

Maximization
maximize_options: difficult, technique (algorithm_spec), iterate (\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance(\#), nonrtolerance, and from (init-specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique (bhhh) resets the default vcetype to vce (opg).
The following options are available with clogit but are not shown in the dialog box:
collinear, coeflegend; see [R] Estimation options.

## Remarks and examples

Remarks are presented under the following headings:

Introduction<br>Matched case-control data<br>Use of weights<br>Fixed-effects logit

## Introduction

clogit fits maximum likelihood models with a dichotomous dependent variable coded as $0 / 1$ (more precisely, clogit interprets 0 and not 0 to indicate the dichotomy). Conditional logistic analysis differs from regular logistic regression in that the data are grouped and the likelihood is calculated relative to each group; that is, a conditional likelihood is used. See Methods and formulas at the end of this entry.

Biostatisticians and epidemiologists call these models conditional logistic regression for matched case-control groups (see, for example, Hosmer, Lemeshow, and Sturdivant [2013, chap. 7]) and fit them when analyzing matched case-control studies with $1: 1$ matching, $1: k_{2 i}$ matching, or $k_{1 i}: k_{2 i}$ matching, where $i$ denotes the $i$ th matched group for $i=1,2, \ldots, n$, where $n$ is the total number of groups. clogit fits a model appropriate for all of these matching schemes or for any mix of the schemes because the matching $k_{1 i}: k_{2 i}$ can vary from group to group. clogit always uses the true conditional likelihood, not an approximation. Biostatisticians and epidemiologists sometimes refer to the matched groups as "strata", but we will stick to the more generic term "group".

Economists and other social scientists typically call the model fit by clogit a fixed-effects logit model for panel data (see, for example, Chamberlain [1980]). The data used to fit a fixed-effects logit model look exactly like the data biostatisticians and epidemiologists call $k_{1 i}: k_{2 i}$ matched case-control data. In terms of how the data are arranged, $k_{1 i}: k_{2 i}$ matching means that in the $i$ th group, the dependent variable is 1 a total of $k_{1 i}$ times and 0 a total of $k_{2 i}$ times. There are a total of $T_{i}=k_{1 i}+k_{2 i}$ observations for the $i$ th group. This data arrangement is what economists and other social scientists call "panel data", "longitudinal data", or "cross-sectional time-series data".

So no matter what terminology you use, the computation and the use of the clogit command is the same. The following example shows how your data should be arranged to use clogit.

## > Example 1

Suppose that we have grouped data with the variable id containing a unique identifier for each group. Our outcome variable, $y$, contains 0 s and 1 s . If we were biostatisticians, $\mathrm{y}=1$ would indicate a case, $\mathrm{y}=0$ would be a control, and id would be an identifier variable that indicates the groups of matched case-control subjects.

If we were economists, $\mathrm{y}=1$ might indicate that a person was unemployed at any time during a year and $\mathrm{y}=0$, that a person was employed all year, and id would be an identifier variable for persons.

If we list the first few observations of this dataset, it looks like

```
. use https://www.stata-press.com/data/r18/clogitid
. list y x1 x2 id in 1/11
```

|  | y | x1 | x 2 | id |
| :---: | :---: | :---: | :---: | :---: |
| 1. | 0 | 0 | 4 | 1014 |
| 2. | 0 | 1 | 4 | 1014 |
| 3. | 0 | 1 | 6 | 1014 |
| 4. | 1 | 1 | 8 | 1014 |
| 5. | 0 | 0 | 1 | 1017 |
| 6. | 0 | 0 | 7 | 1017 |
| 7. | 1 | 1 | 10 | 1017 |
| 8. | 0 | 0 | 1 | 1019 |
| 9. | 0 | 1 | 7 | 1019 |
| 10. | 1 | 1 | 7 | 1019 |
| 11. | 1 | 1 | 9 | 1019 |

Pretending that we are biostatisticians, we describe our data as follows. The first group (id $=1014$ ) consists of four matched persons: 1 case $(\mathrm{y}=1)$ and three controls $(\mathrm{y}=0)$, that is, $1: 3$ matching. The second group has $1: 2$ matching, and the third $2: 2$.

Pretending that we are economists, we describe our data as follows. The first group consists of 4 observations (one per year) for person 1014. This person had a period of unemployment during 1 year of 4 . The second person had a period of unemployment during 1 year of 3 , and the third had a period of 2 years of 4 .

Our independent variables are x 1 and x 2 . To fit the conditional (fixed-effects) logistic model, we type

```
. clogit y x1 x2, group(id)
note: multiple positive outcomes within groups encountered.
Iteration 0: Log likelihood = -123.42828
Iteration 1: Log likelihood = -123.41386
Iteration 2: Log likelihood = -123.41386
Conditional (fixed-effects) logistic regression Number of obs = 369
    LR chi2(2) = 9.07
    Prob > chi2 = 0.0107
    Pseudo R2 = 0.0355
```

| y | Coefficient | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| x1 | .653363 | .2875215 | 2.27 | 0.023 | .0898312 | 1.216895 |
| x 2 | .0659169 | .0449555 | 1.47 | 0.143 | -.0221943 | .1540281 |

## Technical note

The message "note: multiple positive outcomes within groups encountered" at the top of the clogit output for the previous example merely informs us that we have $k_{1 i}: k_{2 i}$ matching with $k_{1 i}>1$ for at least one group. If your data should be $1: k_{2 i}$ matched, this message tells you that there is an error in the data somewhere.

We can see the distribution of $k_{1 i}$ and $T_{i}=k_{1 i}+k_{2 i}$ for the data of the example 1 by using the following steps:

```
. by id, sort: generate k1 = sum(y)
. by id: replace k1 = . if _n < _N
(303 real changes made, 303 to missing)
. by id: generate T = sum(y<.)
. by id: replace T = . if _n < _N
(303 real changes made, 303 to missing)
. tabulate k1
\begin{tabular}{r|rrr} 
k1 & Freq. & Percent & Cum. \\
\hline 1 & 48 & 72.73 & 72.73 \\
2 & 12 & 18.18 & 90.91 \\
3 & 4 & 6.06 & 96.97 \\
4 & 2 & 3.03 & 100.00 \\
\hline Total & 66 & 100.00 &
\end{tabular}
```

. tabulate T

| T | Freq. | Percent | Cum. |
| ---: | ---: | ---: | ---: |
| 2 | 5 | 7.58 | 7.58 |
| 3 | 5 | 7.58 | 15.15 |
| 4 | 12 | 18.18 | 33.33 |
| 5 | 11 | 16.67 | 50.00 |
| 6 | 13 | 19.70 | 69.70 |
| 7 | 8 | 12.12 | 81.82 |
| 8 | 3 | 4.55 | 86.36 |
| 9 | 7 | 10.61 | 96.97 |
| 10 | 2 | 3.03 | 100.00 |
| Total | 66 | 100.00 |  |

We see that $k_{1 i}$ ranges from 1 to 4 and $T_{i}$ ranges from 2 to 10 for these data.

## - Technical note

For $k_{1 i}: k_{2 i}$ matching (and hence in the general case of fixed-effects logit), clogit uses a recursive algorithm to compute the likelihood, which means that there are no limits on the size of $T_{i}$. However, computation time is proportional to $\sum T_{i} \min \left(k_{1 i}, k_{2 i}\right)$, so clogit will take roughly 10 times longer to fit a model with 10:10 matching than one with $1: 10$ matching. But clogit is fast, so computation time becomes an issue only when $\min \left(k_{1 i}, k_{2 i}\right)$ is around 100 or more. See Methods and formulas for details.

## Matched case-control data

Here we give a more detailed example of matched case-control data.

## $>$ Example 2

Hosmer, Lemeshow, and Sturdivant (2013, 24) present data on matched pairs of infants, each pair having one with low birthweight and another with regular birthweight. The data are matched on age of the mother. Several possible maternal exposures are considered: race (three categories), smoking status, presence of hypertension, presence of uterine irritability, previous preterm delivery, and weight at the last menstrual period.

```
. use https://www.stata-press.com/data/r18/lowbirth2, clear
(Applied Logistic Regression, Hosmer & Lemeshow)
. describe
Contains data from https://www.stata-press.com/data/r18/lowbirth2.dta
    Observations: 112 Applied Logistic Regression,
                                    Hosmer & Lemeshow
            Variables: 9 30 Jan 2022 08:46
```

| Variable <br> name | Storage <br> type | Display <br> format | Value <br> label | Variable label |
| :--- | :--- | :--- | :--- | :--- |
| pairid | byte | $\% 8.0 \mathrm{~g}$ |  | Case-control pair ID <br> low byte |
| age | byte | $\% 8.0 \mathrm{~g}$ |  | Baby has low birthweight |
| lwt | int | $\% 8.0 \mathrm{~g}$ |  | Age of mother |
| smoke | byte | $\% 8.0 \mathrm{~g}$ |  | Mother's last menstrual weight |
| ptd | byte | $\% 8.0 \mathrm{~g}$ |  | Mother smoked during pregnancy |
| ht | byte | $\% 8.0 \mathrm{~g}$ |  | Mother had previous preterm baby |
| ui | byte | $\% 8.0 \mathrm{~g}$ |  | Mother has hypertension |
| race | byte | $\% 9.0 \mathrm{~g}$ | race | Uterine irritability |
|  |  |  |  | Race of mother |

Sorted by:
We list the case-control indicator variable, low; the match identifier variable, pairid; and two of the covariates, lwt and smoke, for the first 10 observations.
. list low lwt smoke pairid in $1 / 10$

|  | low | lwt | smoke | pairid |
| ---: | ---: | ---: | ---: | ---: |
| 1. | 0 | 135 | 0 | 1 |
| 2. | 1 | 101 | 1 | 1 |
| 3. | 0 | 98 | 0 | 2 |
| 4. | 1 | 115 | 0 | 2 |
| 5. | 0 | 95 | 0 | 3 |

| 9. | 0 | 122 | 1 | 5 |
| 10. | 1 | 110 | 1 | 5 |

We fit a conditional logistic model of low birthweight on mother's weight, race, smoking behavior, and history.

| Conditional (fixed-effects) logistic regression | Number of obs | $=112$ |
| :---: | :---: | :---: |
|  | LR chi2(7) | $=26.04$ |
|  | Prob > chi2 | $=0.0005$ |
| Log likelihood = -25.794271 | Pseudo R2 | $=0.3355$ |

| low | Coefficient | Std. err. | $z$ | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| lwt | -.0183757 | .0100806 | -1.82 | 0.068 | -.0381333 | .0013819 |
| smoke | 1.400656 | .6278396 | 2.23 | 0.026 | .1701131 | 2.631199 |
| ptd | 1.808009 | .7886502 | 2.29 | 0.022 | .2622828 | 3.353735 |
| ht | 2.361152 | 1.086128 | 2.17 | 0.030 | .2323796 | 4.489924 |
| ui | 1.401929 | .6961585 | 2.01 | 0.044 | .0374836 | 2.766375 |
| race |  |  |  |  |  |  |
| Black | .5713643 | .689645 | 0.83 | 0.407 | -.7803149 | 1.923044 |
| Other | -.0253148 | .6992044 | -0.04 | 0.971 | -1.39573 | 1.345101 |

We might prefer to see results presented as odds ratios. We could have specified the or option when we first fit the model, or we can now redisplay results and specify or:
. clogit, or

| low | Odds ratio | Std. err. | $\mathbf{z}$ | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| lwt | .9817921 | .009897 | -1.82 | 0.068 | .9625847 | 1.001383 |
| smoke | 4.057862 | 2.547686 | 2.23 | 0.026 | 1.185439 | 13.89042 |
| ptd | 6.098293 | 4.80942 | 2.29 | 0.022 | 1.299894 | 28.60938 |
| ht | 10.60316 | 11.51639 | 2.17 | 0.030 | 1.261599 | 89.11467 |
| ui | 4.06303 | 2.828513 | 2.01 | 0.044 | 1.038195 | 15.90088 |
| race |  |  |  |  |  |  |
| Black | 1.770681 | 1.221141 | 0.83 | 0.407 | .4582617 | 6.84175 |
| Other | .975003 | .6817263 | -0.04 | 0.971 | .2476522 | 3.838573 |

Smoking, previous preterm delivery, hypertension, uterine irritability, and possibly the mother's weight all contribute to low birthweight. Race of black and race of other are statistically insignificant when compared with the race of white omitted group, although the race of black effect is large. We can test the joint statistical significance of race being black (2.race) and race being other (3.race) by using test:

```
. test 2.race 3.race
( 1) [low]2.race = 0
( 2) [low]3.race = 0
    chi2( 2) = 0.88
    Prob > chi2 = 0.6436
```

For a more complete description of test, see [R] test. test presents results in coefficients rather than odds ratios. Jointly testing that the coefficients on 2 . race and 3 . race are 0 is equivalent to jointly testing that the odds ratios are 1 .

Here one case was matched to one control, that is, $1: 1$ matching. From clogit's point of view, that was not important - $k_{1}$ cases could have been matched to $k_{2}$ controls ( $k_{1}: k_{2}$ matching), and we would have fit the model in the same way. Furthermore, the matching can change from group to group, which we have denoted as $k_{1 i}: k_{2 i}$ matching, where $i$ denotes the group. clogit does not care. To fit the conditional logistic regression model, we specified the group (varname) option, group(pairid). The case and control are stored in separate observations. clogit knew that they were linked (in the same group) because the related observations share the same value of pairid.

## - Technical note

clogit provides a way to extend McNemar's test to multiple controls per case ( $1: k_{2 i}$ matching) and to multiple controls matched with multiple cases ( $k_{1 i}: k_{2 i}$ matching).

In Stata, McNemar's test is calculated by the mcc command; see [R] Epitab. The mcc command, however, requires that the matched case and control appear in one observation, so the data will need to be manipulated from 1 to 2 observations per stratum before using clogit. Alternatively, if you begin with clogit's 2-observations-per-group organization, you will have to change it to 1 observation per group if you wish to use mcc. In either case, reshape provides an easy way to change the organization of the data. We will demonstrate its use below, but we direct you to [D] reshape for a more thorough discussion.

In example 2, we used clogit to analyze the relationship between low birthweight and various characteristics of the mother. Assume that we now want to assess the relationship between low birthweight and smoking, ignoring the mother's other characteristics. Using clogit, we obtain the following results:

```
. clogit low smoke, group(pairid) or
Iteration 0: Log likelihood = -35.425931
Iteration 1: Log likelihood = -35.419283
Iteration 2: Log likelihood = -35.419282
Conditional (fixed-effects) logistic regression Number of obs = 112
    LR chi2(1) = 6.79
Prob > chi2 = 0.0091
Pseudo R2 = 0.0875
```

| low | Odds ratio | Std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :--- | :---: | :---: | :---: | :---: |
| smoke | 2.75 | 1.135369 | 2.45 | 0.014 | 1.224347 | 6.176763 |

Let's compare our estimated odds ratio and $95 \%$ confidence interval with that produced by mcc. We begin by reshaping the data:

```
. keep low smoke pairid
. reshape wide smoke, i(pairid) j(low 0 1)
\begin{tabular}{lrll} 
Data & Long & \(\rightarrow\) & Wide \\
\hline Number of observations & 112 & \(->\) & 56 \\
Number of variables & 3 & \(\rightarrow\) & 3 \\
j variable (2 values) & low & \(\rightarrow\) & (dropped) \\
xij variables: & smoke & \(\rightarrow\) & smoke0 smoke1 \\
\hline
\end{tabular}
```

We now have the variables smoke0 (formed from smoke and low $=0$ ), recording 1 if the control mother smoked and 0 otherwise; and smoke1 (formed from smoke and low $=1$ ), recording 1 if the case mother smoked and 0 otherwise. We can now use mcc:
. mcc smoke1 smoke0

Both methods estimated the same odds ratio, and the $95 \%$ confidence intervals are similar. clogit produced a confidence interval of $[1.22,6.18]$, whereas mcc produced a confidence interval of [1.18, 7.14 ].

## Use of weights

With clogit, weights apply to groups as a whole, not to individual observations. For example, if there is a group in your dataset with a frequency weight of 3, there are a total of three groups in your sample with the same values of the dependent and independent variables as this one group. Weights must have the same value for all observations belonging to the same group; otherwise, an error message will be displayed.

## > Example 3

We use the example from the above discussion of the mcc command. Here we have a total of 56 matched case-control groups, each with one case matched to one control. We had 8 matched pairs in which both the case and the control are exposed, 22 pairs in which the case is exposed and the control is unexposed, 8 pairs in which the case is unexposed and the control is exposed, and 18 pairs in which they are both unexposed.

With weights, it is easy to enter these data into Stata and run clogit.

```
. clear
. input id case exposed weight
                    id case exposed weight
    1. 11 1 8
    2. 1 0 1 8
    3. 2 1 1 22
    4. 2 0 0 22
    5. 3 1 0 8
    6. 3 0 1 8
    7. 4 1 0 18
    8. 4 0 0 18
    9. end
. clogit case exposed [w=weight], group(id) or
(frequency weights assumed)
Iteration 0: Log likelihood = -35.425931
Iteration 1: Log likelihood = -35.419283
Iteration 2: Log likelihood = -35.419282
Conditional (fixed-effects) logistic regression
Log likelihood = -35.419282
Number of obs = 112
LR chi2(1) = 6.79
Prob > chi2 = 0.0091
Pseudo R2 = 0.0875
```

| case | Odds ratio | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| exposed | 2.75 | 1.135369 | 2.45 | 0.014 | 1.224347 | 6.176763 |

## Fixed-effects logit

The fixed-effects logit model can be written as

$$
\operatorname{Pr}\left(y_{i t}=1 \mid \mathbf{x}_{i t}\right)=F\left(\alpha_{i}+\mathbf{x}_{i t} \boldsymbol{\beta}\right)
$$

where $F$ is the cumulative logistic distribution

$$
F(z)=\frac{\exp (z)}{1+\exp (z)}
$$

$i=1,2, \ldots, n$ denotes the independent units (called "groups" by clogit), and $t=1,2, \ldots, T_{i}$ denotes the observations for the $i$ th unit (group).

Fitting this model by using a full maximum-likelihood approach leads to difficulties, however. When $T_{i}$ is fixed, the maximum likelihood estimates for $\alpha_{i}$ and $\boldsymbol{\beta}$ are inconsistent (Andersen 1970; Chamberlain 1980). This difficulty can be circumvented by looking at the probability of $\mathbf{y}_{i}=$ $\left(y_{i 1}, \ldots, y_{i T_{i}}\right)$ conditional on $\sum_{t=1}^{T_{i}} y_{i t}$. This conditional probability does not involve the $\alpha_{i}$, so they are never estimated when the resulting conditional likelihood is used. See Hamerle and Ronning (1995) for a succinct and lucid development. See Methods and formulas for the estimation equation.

## > Example 4

We are studying unionization of women in the United States by using the union dataset; see [XT] xt. We fit the fixed-effects logit model:

```
. use https://www.stata-press.com/data/r18/union, clear
(NLS Women 14-24 in 1968)
. clogit union age grade not_smsa south black, group(idcode)
note: multiple positive outcomes within groups encountered.
note: 2,744 groups (14,165 obs) omitted because of all positive or
    all negative outcomes.
note: black omitted because of no within-group variance.
Iteration 0: Log likelihood = -4521.3385
Iteration 1: Log likelihood = -4516.1404
Iteration 2: Log likelihood = -4516.1385
Iteration 3: Log likelihood = -4516.1385
Conditional (fixed-effects) logistic regression Number of obs = 12,035
                                    LR chi2(4) = 68.09
                                    Prob > chi2 = 0.0000
Log likelihood = -4516.1385
Pseudo R2 = 0.0075
```

| union | Coefficient | Std. err. | $\mathbf{z}$ | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | ---: | ---: |
| age | .0170301 | .004146 | 4.11 | 0.000 | .0089042 | .0251561 |
| grade | .0853572 | .0418781 | 2.04 | 0.042 | .0032777 | .1674368 |
| not_smsa | .0083678 | .1127963 | 0.07 | 0.941 | -.2127088 | .2294445 |
| south | -.748023 | .1251752 | -5.98 | 0.000 | -.9933619 | -.5026842 |
| black | 0 | (omitted) |  |  |  |  |

We received three messages at the top of the output. The first one, "multiple positive outcomes within groups encountered", we expected. Our data do indeed have multiple positive outcomes (union $=1$ ) in many groups. (Here a group consists of all the observations for a particular individual.)

The second message tells us that 2,744 groups were "omitted" by clogit. When either union $=0$ or union $=1$ for all observations for an individual, this individual's contribution to the log likelihood is zero. Although these are perfectly valid observations in every sense, they have no effect on the estimation, so they are not included in the total "Number of obs". Hence, the reported "Number of obs" gives the effective sample size of the estimation. Here it is 12,035 observations - only $46 \%$ of the total 26,200 .

We can easily check that there are indeed 2,744 groups with union either all 0 or all 1 . We will generate a variable that contains the fraction of observations for each individual who has union $=1$.

```
. by idcode, sort: generate fraction = sum(union)/sum(union < .)
. by idcode: replace fraction = . if _n < _N
(21,766 real changes made, 21,766 to missing)
. tabulate fraction
\begin{tabular}{r|rrr} 
fraction & Freq. & Percent & Cum. \\
\hline 0 & 2,481 & 55.95 & 55.95 \\
.0833333 & 30 & 0.68 & 56.63 \\
.0909091 & 33 & 0.74 & 57.37 \\
.1 & 53 & 1.20 & 58.57 \\
(output omitted ) & & & \\
.9 & 10 & 0.23 & 93.59 \\
.9090909 & 11 & 0.25 & 93.84 \\
.9166667 & 10 & 0.23 & 94.07 \\
1 & 263 & 5.93 & 100.00 \\
\hline Total & 4,434 & 100.00 &
\end{tabular}
```

Because $2481+263=2744$, we confirm what clogit did.
The third warning message from clogit said "black omitted because of no within-group variance". Obviously, race stays constant for an individual across time. Any such variables are collinear with the $\alpha_{i}$ (that is, the fixed effects), and just as the $\alpha_{i}$ drop out of the conditional likelihood, so do all variables that are unchanging within groups. Thus, they cannot be estimated with the conditional fixed-effects model.

There are other estimators implemented in Stata that we could use with these data, such as

```
cloglog ... , vce(cluster idcode)
logit ... , vce(cluster idcode)
probit ... , vce(cluster idcode)
scobit ... , vce(cluster idcode)
xtcloglog ...
xtgee ... , family(binomial) link(logit) corr(exchangeable)
xtlogit ...
xtprobit ...
```

See [R] cloglog, [R] logit, [R] probit, [R] scobit, [XT] xtcloglog, [XT] xtgee, [XT] xtlogit, and [XT] xtprobit for details.

## Stored results

clogit
command as typed
name of dependent variable
name of group() variable
multiple if multiple positive outcomes within group
weight type
weight expression
title in estimation output
name of cluster variable
linear offset variable
Wald or LR; type of model $\chi^{2}$ test
vcetype specified in vce()
title used to label Std. err.
type of optimization
max or min; whether optimizer is to perform maximization or minimization
type of ml method
name of likelihood-evaluator program
maximization technique
b V
program used to implement predict
predictions allowed by margins
predictions disallowed by margins
default predict() specification for margins
factor variables fvset as asbalanced
factor variables fvset as asobserved
coefficient vector
constraints matrix
iteration $\log$ (up to 20 iterations)
gradient vector
variance-covariance matrix of the estimators
model-based variance
marks estimation sample

In addition to the above, the following is stored in r() :

Matrices
r(table)
matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

Breslow and Day (1980, 247-279), Collett (2003, 251-267), and Hosmer, Lemeshow, and Sturdivant (2013, 243-268) provide a biostatistical point of view on conditional logistic regression. Hamerle and Ronning (1995) give a succinct and lucid review of fixed-effects logit; Chamberlain (1980) is a standard reference for this model. Greene (2018, chap. 18) provides a straightforward textbook description of conditional logistic regression from an economist's point of view, as well as a brief description of choice models.

Let $i=1,2, \ldots, n$ denote the groups and let $t=1,2, \ldots, T_{i}$ denote the observations for the $i$ th group. Let $y_{i t}$ be the dependent variable taking on values 0 or 1 . Let $\mathbf{y}_{i}=\left(y_{i 1}, \ldots, y_{i T_{i}}\right)$ be the outcomes for the $i$ th group as a whole. Let $\mathbf{x}_{i t}$ be a row vector of covariates. Let

$$
k_{1 i}=\sum_{t=1}^{T_{i}} y_{i t}
$$

be the observed number of ones for the dependent variable in the $i$ th group. Biostatisticians would say that there are $k_{1 i}$ cases matched to $k_{2 i}=T_{i}-k_{1 i}$ controls in the $i$ th group.

We consider the probability of a possible value of $\mathbf{y}_{i}$ conditional on $\sum_{t=1}^{T_{i}} y_{i t}=k_{1 i}$ (Hamerle and Ronning 1995, eq. 8.33; Hosmer, Lemeshow, and Sturdivant 2013, eq. 7.4),

$$
\operatorname{Pr}\left(\mathbf{y}_{i} \mid \sum_{t=1}^{T_{i}} y_{i t}=k_{1 i}\right)=\frac{\exp \left(\sum_{t=1}^{T_{i}} y_{i t} \mathbf{x}_{i t} \boldsymbol{\beta}\right)}{\sum_{\mathbf{d}_{i} \in S_{i}} \exp \left(\sum_{t=1}^{T_{i}} d_{i t} \mathbf{x}_{i t} \boldsymbol{\beta}\right)}
$$

where $d_{i t}$ is equal to 0 or 1 with $\sum_{t=1}^{T_{i}} d_{i t}=k_{1 i}$, and $S_{i}$ is the set of all possible combinations of $k_{1 i}$ ones and $k_{2 i}$ zeros. Clearly, there are $\binom{T_{i}}{k_{1 i}}$ such combinations, but we need not count all of these combinations to compute the denominator of the above equation. It can be computed recursively.

Denote the denominator by

$$
f_{i}\left(T_{i}, k_{1 i}\right)=\sum_{\mathbf{d}_{i} \in S_{i}} \exp \left(\sum_{t=1}^{T_{i}} d_{i t} \mathbf{x}_{i t} \boldsymbol{\beta}\right)
$$

Consider, computationally, how $f_{i}$ changes as we go from a total of 1 observation in the group to 2 observations to 3 , etc. Doing this, we derive the recursive formula

$$
f_{i}(T, k)=f_{i}(T-1, k)+f_{i}(T-1, k-1) \exp \left(\mathbf{x}_{i T} \boldsymbol{\beta}\right)
$$

where we define $f_{i}(T, k)=0$ if $T<k$ and $f_{i}(T, 0)=1$.

The conditional log-likelihood is

$$
\ln L=\sum_{i=1}^{n}\left\{\sum_{t=1}^{T_{i}} y_{i t} \mathbf{x}_{i t} \boldsymbol{\beta}-\log f_{i}\left(T_{i}, k_{1 i}\right)\right\}
$$

The derivatives of the conditional log-likelihood can also be computed recursively by taking derivatives of the recursive formula for $f_{i}$.

Computation time is roughly proportional to

$$
p^{2} \sum_{i=1}^{n} T_{i} \min \left(k_{1 i}, k_{2 i}\right)
$$

where $p$ is the number of independent variables in the model. If $\min \left(k_{1 i}, k_{2 i}\right)$ is small, computation time is not an issue. But if it is large-say, 100 or more-patience may be required.

If $T_{i}$ is large for all groups, the bias of the unconditional fixed-effects estimator is not a concern, and we can confidently use logit with an indicator variable for each group (provided, of course, that the number of groups is held within a Stata matrix; see [R] Limits).

This command supports the clustered version of the Huber/White/sandwich estimator of the variance using vce (robust) and vce (cluster clustvar). See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas. Specifying vce (robust) is equivalent to specifying vce(cluster groupvar), where groupvar is the variable for the matched groups.
clogit also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

## Title

clogit postestimation - Postestimation tools for clogit

| Postestimation commands | predict | margins |
| :--- | :--- | :--- |
| Remarks and examples | Methods and formulas | Reference |

## Postestimation commands

The following standard postestimation commands are available after clogit:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estat (svy) | postestimation statistics for survey data |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| * hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| linktest | link test for model specification |
| * lrtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | probabilities, influence statistics, residuals, etc. |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| suest | seemingly unrelated estimation |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

[^10]
## predict

## Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, standard errors, influence statistics, lack-of-fit statistics, Hosmer and Lemeshow leverages, Pearson residuals, and the equation-level score.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

statistic Description

Main
pc1 probability of a positive outcome; the default
$\mathrm{puO} \quad$ probability of a positive outcome, assuming fixed effect is zero
$\mathrm{xb} \quad$ linear prediction
stdp standard error of the linear prediction

* dbeta Delta- $\boldsymbol{\beta}$ influence statistic
* dx2 Delta- $\chi^{2}$ lack-of-fit statistic
*gdbeta Delta- $\boldsymbol{\beta}$ influence statistic for each group
* gdx 2

Delta- $\chi^{2}$ lack-of-fit statistic for each group
*hat Hosmer and Lemeshow leverage

* residuals Pearson residuals
* rstandard standardized Pearson residuals
score first derivative of the log likelihood with respect to $\mathbf{x}_{j} \boldsymbol{\beta}$
Unstarred statistics are available both in and out of sample; type predict ... if e (sample) ... if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when if e(sample) is not specified.

Starred statistics are available for multiple controls per case-matching design only. They are not available if vce(robust), vce(cluster clustvar), or pweights were specified with clogit.
dbeta, dx2, gdbeta, gdx2, hat, and rstandard are not available if constraints() was specified with clogit.

## Options for predict

$\qquad$ Main
pc 1 , the default, calculates the probability of a positive outcome conditional on one positive outcome within group.
puO calculates the probability of a positive outcome, assuming that the fixed effect is zero. xb calculates the linear prediction.
stdp calculates the standard error of the linear prediction.
dbeta calculates the Delta- $\boldsymbol{\beta}$ influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation.
dx 2 calculates the Delta- $\chi^{2}$ influence statistic, reflecting the decrease in the Pearson $\chi^{2}$ that is due to deletion of the observation.
gdbeta calculates the approximation to the Pregibon stratum-specific Delta- $\boldsymbol{\beta}$ influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the entire stratum.
gdx2 calculates the approximation to the Pregibon stratum-specific Delta- $\chi^{2}$ influence statistic, reflecting the decrease in the Pearson $\chi^{2}$ that is due to deletion of the entire stratum.
hat calculates the Hosmer and Lemeshow leverage or the diagonal element of the hat matrix.
residuals calculates the Pearson residuals.
rstandard calculates the standardized Pearson residuals.
score calculates the equation-level score, $\partial \ln L / \partial\left(\mathbf{x}_{i t} \boldsymbol{\beta}\right)$.
nooffset is relevant only if you specified offset (varname) for clogit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_{j} \mathbf{b}$ rather than as $\mathbf{x}_{j} \mathbf{b}+$ offset $_{j}$. This option cannot be specified with dbeta, dx2, gdbeta, gdx2, hat, and rstandard.

## margins

## Description for margins

margins estimates margins of response for probabilities and linear predictions.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic Description
pu0 probability of a positive outcome, assuming fixed effect is zero; the default
$\mathrm{xb} \quad$ linear prediction
pc1 not allowed with margins
stdp not allowed with margins
dbeta not allowed with margins
dx2 not allowed with margins
gdbeta not allowed with margins
gdx2 not allowed with margins
hat not allowed with margins
residuals not allowed with margins
rstandard not allowed with margins
score not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

## Remarks and examples

predict may be used after clogit to obtain predicted values of the index $\mathbf{x}_{i t} \boldsymbol{\beta}$. Predicted probabilities for conditional logistic regression must be interpreted carefully. Probabilities are estimated for each group as a whole, not for individual observations. Furthermore, the probabilities are conditional on the number of positive outcomes in the group (that is, the number of cases and the number of controls), or it is assumed that the fixed effect is zero. predict may also be used to obtain influence and lack-of-fit statistics for an individual observation and for the whole group, to compute Pearson, standardized Pearson residuals, and leverage values.
predict may be used for both within-sample and out-of-sample predictions.
> Example 1
Suppose that we have $1: k_{2 i}$ matched data and that we have previously fit the following model:

```
. use https://www.stata-press.com/data/r18/clogitid
. clogit y x1 x2, group(id)
    (output omitted)
```

To obtain the predicted values of the index, we could type predict idx, xb to create a new variable called idx. From idx, we could then calculate the predicted probabilities. Easier, however, would be to type

```
. predict phat
(option pc1 assumed; probability of success given one success within group)
```

phat would then contain the predicted probabilities.
As noted previously, the predicted probabilities are really predicted probabilities for the group as a whole (that is, they are the predicted probability of observing $y_{i t}=1$ and $y_{i t^{\prime}}=0$ for all $t^{\prime} \neq t$ ). Thus, if we want to obtain the predicted probabilities for the estimation sample, it is important that, when we make the calculation, predictions be restricted to the same sample on which we estimated the data. We cannot predict the probabilities and then just keep the relevant ones because the entire sample determines each probability. Thus, assuming that we are not attempting to make out-of-sample predictions, we type

```
. predict phat2 if e(sample)
(option pc1 assumed; probability of success given one success within group)
```

## Methods and formulas

Recall that $i=1, \ldots, n$ denote the groups and $t=1, \ldots, T_{i}$ denote the observations for the $i$ th group.
predict produces probabilities of a positive outcome within group conditional on there being one positive outcome (pc1),

$$
\operatorname{Pr}\left(y_{i t}=1 \mid \sum_{t=1}^{T_{i}} y_{i t}=1\right)=\frac{\exp \left(\mathbf{x}_{i t} \boldsymbol{\beta}\right)}{\sum_{t=1}^{T_{i}} \exp \left(\mathbf{x}_{i t} \boldsymbol{\beta}\right)}
$$

or predict calculates the unconditional pu0:

$$
\operatorname{Pr}\left(y_{i t}=1\right)=\frac{\exp \left(\mathbf{x}_{i t} \boldsymbol{\beta}\right)}{1+\exp \left(\mathbf{x}_{i t} \boldsymbol{\beta}\right)}
$$

Let $N=\sum_{j=1}^{n} T_{j}$ denote the total number of observations, $p$ denote the number of covariates, and $\widehat{\theta}_{i t}$ denote the conditional predicted probabilities of a positive outcome ( pc 1 ).

For the multiple control per case ( $1: k_{2 i}$ ) matching, Hosmer, Lemeshow, and Sturdivant (2013, 248-251) propose the following diagnostics:

The Pearson residual is

$$
r_{i t}=\frac{\left(y_{i t}-\widehat{\theta}_{i t}\right)}{\sqrt{\widehat{\theta}_{i t}}}
$$

The leverage (hat) value is defined as

$$
h_{i t}=\widehat{\theta}_{i t} \widetilde{\mathbf{x}}_{i t}^{T}\left(\widetilde{\mathbf{X}}^{T} \mathbf{U} \widetilde{\mathbf{X}}\right)^{-1} \widetilde{\mathbf{x}}_{i t}
$$

where $\widetilde{\mathbf{x}}_{i t}=\mathbf{x}_{i t}-\sum_{j=1}^{T_{i}} \mathbf{x}_{i j} \widehat{\theta}_{i j}$ is the $1 \times p$ row vector of centered by a weighted stratum-specific mean covariate values, $\mathbf{U}_{N}=\operatorname{diag}\left\{\widehat{\theta}_{i t}\right\}$, and the rows of $\widetilde{\mathbf{X}}_{N \times p}$ are composed of $\widetilde{\mathbf{x}}_{i t}$ values.

The standardized Pearson residual is

$$
r_{s i t}=\frac{r_{i t}}{\sqrt{1-h_{i t}}}
$$

The lack-of-fit and influence diagnostics for an individual observation are (respectively) computed as

$$
\Delta \chi_{i t}^{2}=r_{s i t}^{2}
$$

and

$$
\Delta \widehat{\beta}_{i t}=\Delta \chi_{i t}^{2} \frac{h_{i t}}{1-h_{i t}}
$$

The lack-of-fit and influence diagnostics for the groups are the group-specific totals of the respective individual diagnostics shown above.

## Title

cloglog - Complementary log-log regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| Acknowledgment | References | Also see |  |

## Description

cloglog fits a complementary $\log -\log$ model for a binary dependent variable, typically with one of the outcomes rare relative to the other. It can also be used to fit a gompit model. cloglog can compute robust and cluster-robust standard errors and adjust results for complex survey designs.

## Quick start

Complementary $\log -\log$ model of y on x 1 and x 2
cloglog y x1 x2
With robust standard errors
cloglog y x1 x2, vce(robust)
Adjust for complex survey design using svyset data
svy: cloglog y x1 x2

## Menu

Statistics $>$ Binary outcomes $>$ Complementary log-log regression

## Syntax

cloglog depvar [indepvars] [if] [in] [weight] [, options]
options
Model
noconstant
offset (varname)
asis
constraints (constraints)
SE/Robust
vce (vcetype)

Reporting
level(\#)
eform
nocnsreport
display_options

Description
suppress constant term
include varname in model with coefficient constrained to 1
retain perfect predictor variables
apply specified linear constraints
vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife
set confidence level; default is level (95)
report exponentiated coefficients
do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
control the maximization process; seldom used
keep collinear variables
display legend instead of statistics
indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bayes, bootstrap, by, collect, fmm, fp, jackknife, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: cloglog and [FMM] fmm: cloglog.
vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

[^11]SE/Robust
vce (vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
$\qquad$ Reporting
level (\#); see [R] Estimation options.
eform displays the exponentiated coefficients and corresponding standard errors and confidence intervals.
nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap (\#), fvwrapon(style), cformat( $\%$ fmt), pformat ( $\%$ fint), sformat ( $\% f m t$ ), and nolstretch; see [R] Estimation options.

Maximization
maximize_options: difficult, technique (algorithm_spec), iterate(\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance (\#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique (bhhh) resets the default vcetype to vce (opg).
The following options are available with cloglog but are not shown in the dialog box: collinear, coeflegend; see [R] Estimation options.

## Remarks and examples

Remarks are presented under the following headings:
Introduction to complementary log-log regression Robust standard errors

## Introduction to complementary log-log regression

cloglog fits maximum likelihood models with dichotomous dependent variables coded as $0 / 1$ (or, more precisely, coded as 0 and not 0 ).
> Example 1
We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a model explaining whether a car is foreign based on its weight and mileage. Here is an overview of our data:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. keep make mpg weight foreign
. describe
Contains data from https://www.stata-press.com/data/r18/auto.dta

Total & - & &
\end{tabular}
(2 unique values)
        foreign is labeled and all values are documented in the label.
```

The variable foreign takes on two unique values, 0 and 1 . The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$
\operatorname{Pr}(\text { foreign }=1)=F\left(\beta_{0}+\beta_{1} \text { weight }+\beta_{2} \mathrm{mpg}\right)
$$

where $F(z)=1-\exp \{-\exp (z)\}$.

To fit this model, we type

```
. cloglog foreign weight mpg
Iteration 0: Log likelihood = -34.054593
Iteration 1: Log likelihood = -27.869915
Iteration 2: Log likelihood = -27.742997
Iteration 3: Log likelihood = -27.742769
Iteration 4: Log likelihood = -27.742769
```

Complementary log-log regression $\quad$ Number of obs 74
Zero outcomes $=52$
Nonzero outcomes $=22$
LR chi2(2) $=34.58$
Log likelihood $=-27.742769$
Prob > chi2 $=0.0000$

| foreign | Coefficient | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | ---: | :---: | :---: | ---: | ---: |
| weight | -.0029153 | .0006974 | -4.18 | 0.000 | -.0042823 | -.0015483 |
| mpg | -.1422911 | .076387 | -1.86 | 0.062 | -.2920069 | .0074247 |
| _cons | 10.09694 | 3.351841 | 3.01 | 0.003 | 3.527448 | 16.66642 |

We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least when holding the weight of the car constant.

See [R] Maximize for an explanation of the output.

## Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus, if your dependent variable takes on the values 0 and 1,0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0,1 , and 2,0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type cloglog $y x$, Stata fits the model

$$
\operatorname{Pr}\left(y_{j} \neq 0 \mid \mathbf{x}_{j}\right)=1-\exp \left\{-\exp \left(\mathbf{x}_{j} \boldsymbol{\beta}\right)\right\}
$$

## Robust standard errors

If you specify the vce (robust) option, cloglog reports robust standard errors, as described in [U] 20.22 Obtaining robust variance estimates. For the model of foreign on weight and mpg, the robust calculation increases the standard error of the coefficient on mpg by $44 \%$ :

Without vce (robust), the standard error for the coefficient on mpg was reported to be 0.076 , with a resulting confidence interval of $[-0.29,0.01]$.

The vce(cluster clustvar) option can relax the independence assumption required by the complementary log-log estimator to being just independence between clusters. To demonstrate this ability, we will switch to a different dataset.

We are studying unionization of women in the United States by using the union dataset; see [XT] xt. We fit the following model, ignoring that women are observed an average of 5.9 times each in this dataset:

The reported standard errors in this model are probably meaningless. Women are observed repeatedly, and so the observations are not independent. Looking at the coefficients, we find a large southern
effect against unionization and a different time trend for the south. The vce(cluster clustvar) option provides a way to fit this model and obtains correct standard errors:

These standard errors are larger than those reported by the inappropriate conventional calculation. By comparison, another way we could fit this model is with an equal-correlation population-averaged complementary log-log model:

| GEE population-averaged model | Number of obs | = 26,200 |
| :---: | :---: | :---: |
| Group variable: idcode | Number of groups | $=4,434$ |
| Family: Binomial | Obs per group: |  |
| Link: Complementary log-log | min | $=1$ |
| Correlation: exchangeable | avg | $=5.9$ |
|  | max | 12 |
|  | Wald chi2(6) | $=234.66$ |
| Scale parameter = 1 | Prob > chi2 | $=0.0000$ |

| union | Coefficient | Std. err. | $z$ | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| age | .0153737 | .0081156 | 1.89 | 0.058 | -.0005326 | .03128 |
| grade | .0549518 | .0095093 | 5.78 | 0.000 | .0363139 | .0735897 |
| not_smsa | -.1045232 | .0431082 | -2.42 | 0.015 | -.1890138 | -.0200326 |
| 1.south | -1.714868 | .3384558 | -5.07 | 0.000 | -2.378229 | -1.051507 |
| year | -.0115881 | .0084125 | -1.38 | 0.168 | -.0280763 | .0049001 |
| south\#c.year |  |  |  |  |  |  |
| 1 | .0149796 | .0041687 | 3.59 | 0.000 | .0068091 | .0231501 |
| _cons | -1.488278 | .4468005 | -3.33 | 0.001 | -2.363991 | -.6125652 |

The coefficient estimates are similar, but these standard errors are smaller than those produced by cloglog, vce (cluster clustvar). This finding is as we would expect. If the within-panel correlation assumptions are valid, the population-averaged estimator should be more efficient.

In addition to this estimator, we may use the xtgee command to fit a panel estimator (with complementary $\log -\log$ link) and any number of assumptions on the within-idcode correlation.
cloglog, vce(cluster clustvar) is robust to assumptions about within-cluster correlation. That is, it inefficiently sums within cluster for the standard error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation (as do the xtgee population-averaged models).

## Stored results

cloglog stores the following in e():

In addition to the above, the following is stored in r() :

## Matrices

$r$ (table) matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

Complementary log-log analysis (related to the gompit model, so named because of its relationship to the Gompertz distribution) is an alternative to logit and probit analysis, but it is unlike these other estimators in that the transformation is not symmetric. Typically, this model is used when the positive (or negative) outcome is rare.

The log-likelihood function for complementary $\log -\log$ is

$$
\ln L=\sum_{j \in S} w_{j} \ln F\left(\mathbf{x}_{j} \mathbf{b}\right)+\sum_{j \notin S} w_{j} \ln \left\{1-F\left(\mathbf{x}_{j} \mathbf{b}\right)\right\}
$$

where $S$ is the set of all observations $j$ such that $y_{j} \neq 0, F(z)=1-\exp \{-\exp (z)\}$, and $w_{j}$ denotes the optional weights. $\ln L$ is maximized as described in [ R$]$ Maximize.

We can fit a gompit model by reversing the success-failure sense of the dependent variable and using cloglog.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce (robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas. The scores are calculated as $\mathbf{u}_{j}=$ $\left[\exp \left(\mathbf{x}_{j} \mathbf{b}\right) \exp \left\{-\exp \left(\mathbf{x}_{j} \mathbf{b}\right)\right\} / F\left(\mathbf{x}_{j} \mathbf{b}\right)\right] \mathbf{x}_{j}$ for the positive outcomes and $\left\{-\exp \left(\mathbf{x}_{j} \mathbf{b}\right)\right\} \mathbf{x}_{j}$ for the negative outcomes.
cloglog also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

## Acknowledgment

We thank Joseph Hilbe (1944-2017), coauthor of the Stata Press book Generalized Linear Models and Extensions, for providing the inspiration for the cloglog command.

## Postestimation commands

The following postestimation commands are available after cloglog:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estat (svy) | postestimation statistics for survey data |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| * forecast | dynamic forecasts and simulations |
| * hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| linktest | link test for model specification |
| * Irtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | probabilities, linear predictions and their SEs, etc. |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| suest | seemingly unrelated estimation |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

[^12]
## predict

## Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, standard errors, and the equation-level score.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

predict [type] newvar [if][in] [, statistic nooffset]
statistic
Description
Main
$\mathrm{pr} \quad$ probability of a positive outcome; the default
$\mathrm{xb} \quad$ linear prediction
stdp standard error of the linear prediction
score first derivative of the $\log$ likelihood with respect to $\mathbf{x}_{j} \boldsymbol{\beta}$
These statistics are available both in and out of sample; type predict ... if e(sample)... if wanted only for the estimation sample.

## Options for predict

Main
pr , the default, calculates the probability of a positive outcome.
xb calculates the linear prediction.
stdp calculates the standard error of the linear prediction.
score calculates the equation-level score, $\partial \ln L / \partial\left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$.
nooffset is relevant only if you specified offset (varname) for cloglog. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_{j} \mathbf{b}$ rather than as $\mathbf{x}_{j} \mathbf{b}+$ offset $_{j}$.

## margins

## Description for margins

margins estimates margins of response for probabilities and linear predictions.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

margins [marginlist] [, options]

statistic Description
$\mathrm{pr} \quad$ probability of a positive outcome; the default
xb linear prediction
stdp not allowed with margins
score not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see $[R]$ margins.

## Remarks and examples

Once you have fit a model, you can obtain the predicted probabilities by using the predict command for both the estimation sample and other samples; see [U] 20 Estimation and postestimation commands and $[\mathrm{R}]$ predict. Here we will make only a few comments.
predict without arguments calculates the predicted probability of a positive outcome. With the xb option, it calculates the linear combination $\mathbf{x}_{j} \mathbf{b}$, where $\mathbf{x}_{j}$ are the independent variables in the $j$ th observation and $\mathbf{b}$ is the estimated parameter vector.

With the stdp option, predict calculates the standard error of the linear prediction, which is not adjusted for replicated covariate patterns in the data.
> Example 1
In example 1 in [ R$]$ cloglog, we fit the complementary $\log -\log$ model cloglog foreign weight mpg . To obtain predicted probabilities,

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. cloglog foreign weight mpg
    (output omitted)
- predict p
(option pr assumed; Pr(foreign))
. summarize foreign p
\begin{tabular}{r|rrrrr} 
Variable & Obs & Mean & Std. dev. & Min & Max \\
\hline foreign & 74 & .2972973 & .4601885 & 0 & 1 \\
\(p\) & 74 & .2928348 & .29732 & .0032726 & .9446067
\end{tabular}
```

cnsreg - Constrained linear regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

cnsreg fits constrained linear regression models.

## Quick start

Linear regression with coefficients for x 1 and x 2 constrained to equality
constraint $1 \mathrm{x} 1=\mathrm{x} 2$
cnsreg y x1 x2 x3, constraints(1)
Add constraint $x 2=x 3$ to impose $x 1=x 2=x 3$
constraint $2 \times 2=x 3$
cnsreg y x1 x2 x3, constraints(1 2)
Constrain the coefficient for x 4 to be -1
constraint $3 \times 4=-1$
cnsreg y x1 x2 x3 x4, constraints(1-3)

## Menu

Statistics $>$ Linear models and related $>$ Constrained linear regression

## Syntax

cnsreg depvar indepvars [if][in] [weight], constraints(constraints) [options] options Description

## Model

* constraints (constraints)
noconstant
SE/Robust
vce (vcetype)

Reporting
level(\#)
nocnsreport
display_options
mse1
collinear
coeflegend
apply specified linear constraints
suppress constant term
vcetype may be ols, robust, cluster clustvar, bootstrap, or jackknife
set confidence level; default is level (95)
do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
force MSE to be 1
keep collinear variables
display legend instead of statistics
*constraints (constraints) is required.
indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bootstrap, by, collect, fp, jackknife, mi estimate, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.
vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
With the fp prefix (see $[\mathrm{R}] \mathrm{fp}$ ), constraints cannot be specified for the variable containing fractional polynomial terms. Weights are not allowed with the bootstrap prefix; see $[\mathrm{R}]$ bootstrap.
aweights are not allowed with the jackknife prefix; see $[R]$ jackknife.
vce(), mse1, and weights are not allowed with the svy prefix; see [SVY] svy.
aweights, fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
mse1, collinear, and coeflegend do not appear in the dialog.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

Model
constraints(constraints), noconstant; see [R] Estimation options.

## SE/Robust

vce (vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (ols), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
vce(ols), the default, uses the standard variance estimator for ordinary least-squares regression.
level(\#), nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% fint), and nolstretch; see [R] Estimation options.

The following options are available with ensreg but are not shown in the dialog box:
mse1 is used only in programs and ado-files that use cnsreg to fit models other than constrained linear regression. mse1 sets the mean squared error to 1 , thus forcing the variance-covariance matrix of the estimators to be $\left(\mathbf{X}^{\prime} \mathbf{D X}\right)^{-1}$ (see Methods and formulas in $[\mathrm{R}]$ regress) and affecting calculated standard errors. Degrees of freedom for $t$ statistics are calculated as $n$ rather than $n-p+c$, where $p$ is the total number of parameters (prior to restrictions and including the constant) and $c$ is the number of constraints.
mse1 is not allowed with the svy prefix.
collinear, coeflegend; see [R] Estimation options.

## Remarks and examples

For a discussion of constrained linear regression, see Greene (2018, 126-127); Hill, Griffiths, and Lim (2018, 271-273); or Davidson and MacKinnon (1993, 17).

## > Example 1: One constraint

In principle, we can obtain constrained linear regression estimates by modifying the list of independent variables. For instance, if we wanted to fit the model

$$
\operatorname{mpg}=\beta_{0}+\beta_{1} \text { price }+\beta_{2} \text { weight }+u
$$

and constrain $\beta_{1}=\beta_{2}$, we could write

$$
\operatorname{mpg}=\beta_{0}+\beta_{1}(\text { price }+ \text { weight })+u
$$

and run a regression of mpg on price + weight. The estimated coefficient on the sum would be the constrained estimate of $\beta_{1}$ and $\beta_{2}$. Using cnsreg, however, is easier:

| (1978 automobile data) <br> . constraint 1 price = weight <br> . cnsreg mpg price weight, constraint(1) |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Constrained linear regression |  |  |  |  | $\begin{array}{llr} \text { Number of obs } & =74 \\ \mathrm{~F}(1,72) & =37.59 \\ \text { Prob }>\mathrm{F} & =0.0000 \\ \text { Root MSE } & =4.7220 \end{array}$ |  |
|  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |
| ( 1) price - weight $=0$ |  |  |  |  |  |  |
| mpg | Coefficient | Std. err. | t | $P>\|t\|$ | [95\% conf | interval] |
| price | -. 0009875 | . 0001611 | -6.13 | 0.000 | -. 0013086 | -. 0006664 |
| weight | -. 0009875 | . 0001611 | -6.13 | 0.000 | -. 0013086 | -. 0006664 |
| _cons | 30.36718 | 1.577958 | 19.24 | 0.000 | 27.22158 | 33.51278 |

We define constraints by using the constraint command; see [R] constraint. We fit the model with cnsreg and specify the constraint number or numbers in the constraints() option.

Just to show that the results above are correct, here is the result of applying the constraint by hand:

```
. generate x = price + weight
. regress mpg x
```

| Source | SS | df | MS | Number of obs | = | 74 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathrm{F}(1,72)$ | = | 37.59 |
| Model | 838.065767 | 1 | 838.065767 | Prob > F | = | 0.0000 |
| Residual | 1605.39369 | 72 | 22.2971346 | R -squared | = | 0.3430 |
|  |  |  |  | Adj R-squared | = | 0.3339 |
| Total | 2443.45946 | 73 | 33.4720474 | Root MSE | = | 4.722 |

| mpg | Coefficient | Std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | :---: | :---: | ---: | ---: |
| x | -.0009875 | .0001611 | -6.13 | 0.000 | -.0013086 | -.0006664 |
| _cons | 30.36718 | 1.577958 | 19.24 | 0.000 | 27.22158 | 33.51278 |

## $>$ Example 2: Multiple constraints

Models can be fit subject to multiple simultaneous constraints. We simply define the constraints and then include the constraint numbers in the constraints() option. For instance, say that we wish to fit the model

$$
\begin{aligned}
\operatorname{mpg}= & \beta_{0}+\beta_{1} \text { price }+\beta_{2} \text { weight }+\beta_{3} \text { displ }+\beta_{4} \text { gear_ratio }+\beta_{5} \text { foreign }+ \\
& \beta_{6} \text { length }+u
\end{aligned}
$$

subject to the constraints

$$
\begin{aligned}
& \beta_{1}=\beta_{2}=\beta_{3}=\beta_{6} \\
& \beta_{4}=-\beta_{5}=\beta_{0} / 20
\end{aligned}
$$

(This model, like the one in example 1, is admittedly senseless.) We fit the model by typing

```
. constraint 1 price=weight
. constraint 2 displ=weight
. constraint 3 length=weight
. constraint 5 gear_ratio = -foreign
. constraint 6 gear_ratio = _cons/20
```

```
    ( 1) price - weight = 0
    ( 2) - weight + displacement = 0
    ( 3) - weight + length = 0
    ( 4) gear_ratio + foreign = 0
    ( 5) gear_ratio - .05*_cons = 0
```

. cnsreg mpg price weight displ gear_ratio foreign length, $c(1-3,5-6)$
Constrained linear regression $\quad$ Number of obs $=\quad 74$
$\mathrm{F}(2,72)=785.20$
Prob > F $\quad=0.0000$
Root MSE $=4.6823$

| mpg | Coefficient | Std. err. | t | P>\|t| | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | ---: | ---: |
| price | -.000923 | .0001534 | -6.02 | 0.000 | -.0012288 | -.0006172 |
| weight | -.000923 | .0001534 | -6.02 | 0.000 | -.0012288 | -.0006172 |
| displacement | -.000923 | .0001534 | -6.02 | 0.000 | -.0012288 | -.0006172 |
| gear_ratio | 1.326114 | .0687589 | 19.29 | 0.000 | 1.189046 | 1.463183 |

There are many ways we could have specified the constraints() option (which we abbreviated $c()$ above $)$. We typed $c(1-3,5-6)$, meaning that we want constraints 1 through 3 and 5 and 6 ; those numbers correspond to the constraints we defined. The only reason we did not use the number 4 was to emphasize that constraints do not have to be consecutively numbered. We typed $c(1-3,5-6)$, but we could have typed $c(1,2,3,5,6)$ or $c(1-3,5,6)$ or $c(1-2,3,5,6)$ or even $c(1-6)$, which would have worked as long as constraint 4 was not defined. If we had previously defined a constraint 4 , then $c(1-6)$ would have included it.

## Stored results

cnsreg stores the following in e() :
Scalars
e(N)
$e\left(d f \_m\right)$
e(df_r)
e(F)
e(p)
e(rmse)

In addition to the above, the following is stored in r() :

```
Matrices
```

    \(r\) (table) matrix containing the coefficients with their standard errors, test statistics, \(p\)-values,
    and confidence intervals
    Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

Let $n$ be the number of observations, $p$ be the total number of parameters (prior to restrictions and including the constant), and $c$ be the number of constraints. The coefficients are calculated as $\mathbf{b}^{\prime}=\mathbf{T}\left\{\left(\mathbf{T}^{\prime} \mathbf{X}^{\prime} \mathbf{W} \mathbf{X} \mathbf{T}\right)^{-1}\left(\mathbf{T}^{\prime} \mathbf{X}^{\prime} \mathbf{W} \mathbf{y}-\mathbf{T}^{\prime} \mathbf{X}^{\prime} \mathbf{W} \mathbf{X a} \mathbf{a}^{\prime}\right)\right\}+\mathbf{a}^{\prime}$, where $\mathbf{T}$ and $\mathbf{a}$ are as defined in $[\mathrm{P}]$ makecns. $\mathbf{W}=\mathbf{I}$ if no weights are specified. If weights are specified, let $\mathbf{v}: 1 \times n$ be the specified weights. If fweight frequency weights are specified, $\mathbf{W}=\operatorname{diag}(\mathbf{v})$. If aweight analytic weights are specified, then $\mathbf{W}=\operatorname{diag}\left[\mathbf{v} /\left(\mathbf{1}^{\prime} \mathbf{v}\right)\left(\mathbf{1}^{\prime} \mathbf{1}\right)\right]$, meaning that the weights are normalized to sum to the number of observations.

The mean squared error is $s^{2}=\left(\mathbf{y}^{\prime} \mathbf{W} \mathbf{y}-2 \mathbf{b}^{\prime} \mathbf{X}^{\prime} \mathbf{W} \mathbf{y}+\mathbf{b}^{\prime} \mathbf{X}^{\prime} \mathbf{W} \mathbf{X} \mathbf{b}\right) /(n-p+c)$. The variance covariance matrix is $s^{2} \mathbf{T}\left(\mathbf{T}^{\prime} \mathbf{X}^{\prime} \mathbf{W} \mathbf{X} \mathbf{T}\right)^{-1} \mathbf{T}^{\prime}$.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce (robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Introduction and Methods and formulas.
cnsreg also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

cnsreg postestimation - Postestimation tools for cnsreg

Postestimation commands predict margins Also see

## Postestimation commands

The following postestimation commands are available after cnsreg:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estat (svy) | postestimation statistics for survey data |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| * forecast | dynamic forecasts and simulations |
| * hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| linktest | link test for model specification |
| * 1 rtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | predictions and their SEs, residuals, etc. |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| suest | seemingly unrelated estimation |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

[^13]
## predict

## Description for predict

predict creates a new variable containing predictions such as linear predictions, residuals, standard errors, probabilities, and expected values.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

statistic Description

Main
$\mathrm{xb} \quad$ linear prediction; the default
residuals residuals
stdp standard error of the prediction
stdf standard error of the forecast
$\operatorname{pr}(a, b) \quad \operatorname{Pr}\left(a<y_{j}<b\right)$
$\mathrm{e}(a, b) \quad E\left(y_{j} \mid a<y_{j}<b\right)$
$\underline{\operatorname{ystar}(a, b)} \quad E\left(y_{j}^{*}\right), y_{j}^{*}=\max \left\{a, \min \left(y_{j}, b\right)\right\}$
score equivalent to residuals

These statistics are available both in and out of sample; type predict . . . if e (sample) ... if wanted only for the estimation sample.
stdf is not allowed with svy estimation results.
where $a$ and $b$ may be numbers or variables; $a$ missing ( $a \geq$.) means $-\infty$, and $b$ missing ( $b \geq$.) means $+\infty$; see [U] 12.2.1 Missing values.

## Options for predict

$\qquad$ Main
xb , the default, calculates the linear prediction.
residuals calculates the residuals, that is, $y_{j}-\mathbf{x}_{j} \mathbf{b}$.
stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.
stdf calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by stdf are always larger than those produced by stdp; see Methods and formulas in [R] regress postestimation.
$\operatorname{pr}(a, b)$ calculates $\operatorname{Pr}\left(a<\mathbf{x}_{j} \mathbf{b}+u_{j}<b\right)$, the probability that $y_{j} \mid \mathbf{x}_{j}$ would be observed in the interval $(a, b)$.
$a$ and $b$ may be specified as numbers or variable names; $l b$ and $u b$ are variable names;
$\operatorname{pr}(20,30)$ calculates $\operatorname{Pr}\left(20<\mathbf{x}_{j} \mathbf{b}+u_{j}<30\right)$;
$\operatorname{pr}(l b, u b)$ calculates $\operatorname{Pr}\left(l b<\mathbf{x}_{j} \mathbf{b}+u_{j}<u b\right)$; and
$\operatorname{pr}(20, u b)$ calculates $\operatorname{Pr}\left(20<\mathbf{x}_{j} \mathbf{b}+u_{j}<u b\right)$.
$a$ missing $(a \geq$.$) means -\infty ; \operatorname{pr}(., 30)$ calculates $\operatorname{Pr}\left(-\infty<\mathbf{x}_{j} \mathbf{b}+u_{j}<30\right)$;
$\operatorname{pr}(l b, 30)$ calculates $\operatorname{Pr}\left(-\infty<\mathbf{x}_{j} \mathbf{b}+u_{j}<30\right)$ in observations for which $l b \geq$.
and calculates $\operatorname{Pr}\left(l b<\mathbf{x}_{j} \mathbf{b}+u_{j}<30\right)$ elsewhere.
$b$ missing ( $b \geq$.) means $+\infty$; $\operatorname{pr}(20,$.$) calculates \operatorname{Pr}\left(+\infty>\mathbf{x}_{j} \mathbf{b}+u_{j}>20\right)$;
$\operatorname{pr}(20, u b)$ calculates $\operatorname{Pr}\left(+\infty>\mathbf{x}_{j} \mathbf{b}+u_{j}>20\right)$ in observations for which $u b \geq$.
and calculates $\operatorname{Pr}\left(20<\mathbf{x}_{j} \mathbf{b}+u_{j}<u b\right)$ elsewhere.
$\mathrm{e}(a, b)$ calculates $E\left(\mathbf{x}_{j} \mathbf{b}+u_{j} \mid a<\mathbf{x}_{j} \mathbf{b}+u_{j}<b\right)$, the expected value of $y_{j} \mid \mathbf{x}_{j}$ conditional on $y_{j} \mid \mathbf{x}_{j}$ being in the interval $(a, b)$, meaning that $y_{j} \mid \mathbf{x}_{j}$ is truncated. $a$ and $b$ are specified as they are for pr() .
ystar $(a, b)$ calculates $E\left(y_{j}^{*}\right)$, where $y_{j}^{*}=a$ if $\mathbf{x}_{j} \mathbf{b}+u_{j} \leq a, y_{j}^{*}=b$ if $\mathbf{x}_{j} \mathbf{b}+u_{j} \geq b$, and $y_{j}^{*}=\mathbf{x}_{j} \mathbf{b}+u_{j}$ otherwise, meaning that $y_{j}^{*}$ is censored. $a$ and $b$ are specified as they are for pr() . score is equivalent to residuals for linear regression models.

## margins

## Description for margins

margins estimates margins of response for linear predictions, probabilities, and expected values.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...)...] [options]
```

statistic Description
$\mathrm{xb} \quad$ linear prediction; the default
$\operatorname{pr}(a, b) \quad \operatorname{Pr}\left(a<y_{j}<b\right)$
$\mathrm{e}(a, b) \quad E\left(y_{j} \mid a<y_{j}<b\right)$
ystar $(a, b) \quad E\left(y_{j}^{*}\right), y_{j}^{*}=\max \left\{a, \min \left(y_{j}, b\right)\right\}$
stdp not allowed with margins
stdf not allowed with margins
residuals not allowed with margins
score not allowed with margins
Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see $[R]$ margins.

## Title

constraint - Define and list constraints

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Remarks and examples | Reference | Also see |  |

## Description

constraint defines, lists, and drops linear constraints. Constraints are for use by models that allow constrained estimation.

Constraints are defined by the constraint command. The currently defined constraints can be listed by either constraint list or constraint dir; both do the same thing. Existing constraints can be eliminated by constraint drop.
constraint get and constraint free are programmer's commands. constraint get returns the contents of the specified constraint in macro $r$ (contents) and returns in scalar $r$ (defined) 0 or $1-1$ being returned if the constraint was defined. constraint free returns the number of a free (unused) constraint in macro $r$ (free).

## Quick start

## For single-equation models

Define constraint 1 to constrain the coefficient for x 1 to 0
constraint define $1 \times 1=0$
Same as above
constraint 1 x 1
Constrain coefficients for x 1 and x 2 to 0
constraint 2 x 1 x 2
Overwrite constraint 2 to constrain x 2 and x 3 to equality
constraint $2 \times 2=x 3$
Constrain the coefficients for factor indicators 2 .a and 3.a to equality
constraint 32 .a $=3 . \mathrm{a}$
Constrain the coefficient on x 1 to equal 1
constraint $4 \mathrm{x} 1=1$

## For multiple-equation models

Constrain coefficient for x 4 to 0 in all equations
constraint 11 x 4
Constrain coefficients for x 4 and x 5 to equality in the equation for y 2
constraint 12 [y2]x4 = [y2]x5

Constrain the coefficient for x 5 to equality in equations for y 1 and y 2
constraint 13 [y1=y2] x5
Constrain coefficient for x 1 to 0 in equation where the dependent variable equals cat2
constraint 14 [cat2] x 1
Constrain the coefficients for factor indicators $1 . \mathrm{a}$ and $1 . \mathrm{b}$ to equality in the equation for category cat3
constraint 15 [cat3]: 1.a $=1 . \mathrm{b}$
Constrain coefficients for x 1 to equality in the equations for categories cat2 and cat3 constraint 16 [cat2=cat3]: x1

Listing constraints
List existing constraints
constraint dir
Same as above
constraint list

## Menu

Statistics $>$ Other $>$ Manage constraints

## Syntax

Define constraints

```
constraint [\underline{define] # [ exp=exp coeflist]}
```

List constraints

```
constraint dir [numlist|_all]
constraint list [numlist|_all]
```

Drop constraints

```
constraint drop {numlist|_all }
```

Programmer's commands

```
constraint get #
constraint free
```

where coeflist is as defined in $[\mathrm{R}]$ test and \# is restricted to the range 1 to 1,999 , inclusive.

## Remarks and examples

Using constraints is discussed in [R] ensreg, $[R]$ mlogit, and $[R]$ reg3; this entry is concerned only with practical aspects of defining and manipulating constraints.

## > Example 1

Constraints are numbered from 1 to 1,999 , and we assign the number when we define the constraint:

```
. use https://www.stata-press.com/data/r18/sysdsn1
(Health insurance data)
. constraint 2 [indemnity]2.site = 0
```

The currently defined constraints can be listed by constraint list:
. constraint list
2: [indemnity]2.site $=0$
constraint drop drops constraints:
. constraint drop 2
. constraint list
The empty list after constraint list indicates that no constraints are defined. Below, we demonstrate the various syntaxes allowed by constraint:
. constraint 1 [Indemnity]
. constraint 10 [Indemnity]: 1.site 2.site
. constraint 11 [Indemnity]: 3.site

```
. constraint 21 [Prepaid=Uninsure]: nonwhite
. constraint 30 [Prepaid]
. constraint 31 [Insure]
. constraint list
        1: [Indemnity]
    10: [Indemnity]: 1.site 2.site
    11: [Indemnity]: 3.site
    21: [Prepaid=Uninsure]: nonwhite
    30: [Prepaid]
    31: [Insure]
. constraint drop 21-25, 31
. constraint list
        1: [Indemnity]
    10: [Indemnity]: 1.site 2.site
    11: [Indemnity]: 3.site
    30: [Prepaid]
. constraint drop _all
. constraint list
```

## Technical note

The constraint command does not check the syntax of the constraint itself because a constraint can be interpreted only in the context of a model. Thus, constraint is willing to define constraints that later will not make sense. Any errors in the constraints will be detected and mentioned at the time of estimation.

## Title

contrast - Contrasts and linear hypothesis tests after estimation

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

contrast tests linear hypotheses and forms contrasts involving factor variables and their interactions from the most recently fit model. The tests include ANOVA-style tests of main effects, simple effects, interactions, and nested effects. contrast can use named contrasts to decompose these effects into comparisons against reference categories, comparisons of adjacent levels, comparisons against the grand mean, orthogonal polynomials, and such. Custom contrasts may also be specified.
contrast can be used with svy estimation results; see [SVY] svy postestimation.
Contrasts can also be computed for margins of linear and nonlinear responses; see [R] margins, contrast.

## Quick start

Contrasts for one-way models
Test the main effect of categorical variable a after regress y i.a or anova y a contrast a

Reference category contrasts of cell means of $y$ with the smallest value of a as the base category contrast r.a

Same as above, but specify $\mathrm{a}=3$ as the base category for comparisons
contrast rb3.a
Report tests instead of confidence intervals for each contrast
contrast r.a, pveffects
Report tests and confidence intervals for each contrast
contrast r.a, effects
Contrasts of the cell mean of $y$ for each level of a with the grand mean of $y$
contrast g.a
Same as above, but compute grand mean as a weighted average of cell means with weights based on the number of observations for each level of a

```
contrast gw.a
```

User-defined contrast comparing the cell mean of y for $\mathrm{a}=1$ with the average of the cell means for

```
a}=3\mathrm{ and a = 4
    contrast {a -1 0 .5 .5}
```

## Contrasts for two-way models

Test of the interaction effect after regress y a\#\#b or anova y a\#\#b
contrast a\#b
Test of the main and interaction effects

```
contrast a b a#b
```

Same as above

```
    contrast a##b
```

Individual reference category contrasts for the interaction of $a$ and $b$

```
    contrast r.a#r.b
```

Joint tests of the simple effects of a within each level of $b$ contrast a@b

Individual reference category contrasts for the simple effects of $a$ within each level of $b$ contrast r.a@b

Orthogonal polynomial contrasts for a within each level of $b$
contrast p.a@b
Reference category contrasts of the marginal means of $y$ for levels of a contrast r.a

Same as above, but with marginal means for a computed as a weighted average of cell means, using the marginal frequencies of $b$ rather than equal weights for each level
contrast r.a, asobserved
Contrasts of the marginal mean of $y$ for each level of a with the previous level-reverse-adjacent contrasts

```
contrast ar.a
```

Contrasts for models with continuous covariates
Test of the interaction effect after regress y a\#\#c.x or anova y a\#\#c.x
contrast a\#c.x
Reference category effects of a on the slope of $x$
contrast r.a\#c.x
Reference category effects of a on the intercept

```
    contrast r.a
```

## Contrasts for nonlinear models

Orthogonal polynomial contrasts of log odds across levels of a after logit y i.a

```
contrast p.a
```

Test the main and interaction effects after logit y a\#\#b

Simple reference category effects for $a$ within each level of $b$ contrast r.a@b

Contrasts for multiple-equation models
Test the main and interaction effects in the equation for y 2 after mvreg y1 y2 y3 $=\mathrm{a} \# \# \mathrm{~b}$ contrast $a \# \# b$, equation(y2)

Reference category contrasts of estimated marginal means of $y 3$ for levels of a contrast r.a, equation(y3)

Test for a difference in the overall estimated marginal means of $\mathrm{y} 1, \mathrm{y} 2$, and y3 contrast _eqns

Contrasts of estimated marginal means of y2 and y3 with y1 contrast r._eqns

Test whether interaction effects differ across equations
contrast a\#b\#_eqns

## Menu

Statistics $>$ Postestimation

## Syntax

```
contrast termlist [, options]
```

where termlist is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without contrast operators, and you may use any factor-variable syntax:

See the operators (op.) table below for the list of contrast operators.
options Description

joint test of the interaction effects of $A$ and $B$ on the slopes of the product (interaction) of x and y
individual contrasts of A's effects on the slopes of x using $r$.
Denominators
... / term2
use term 2 as the denominator in the $F$ tests of the preceding terms
... / use the residual as the denominator in the $F$ tests of the preceding terms (the default if no other /s are specified)
$\mathrm{A}, \mathrm{B}, \mathrm{C}$, and D represent any factor variable in the current estimation results.
x and y represent any continuous variable in the current estimation results.
$r$. and $g$. represent any contrast operator. See the table below.
c. specifies that a variable be treated as continuous; see [U] 11.4.3 Factor variables.

Operators are allowed on any factor variable that does not appear to the right of @ or I. Operators decompose the effects of the associated factor variable into one-degree-of-freedom effects (contrasts).
Higher-level interactions are allowed anywhere an interaction operator (\#) appears in the table.
Time-series operators are allowed if they were used in the estimation.
_eqns designates the equations in manova, mlogit, mprobit, and mvreg and can be specified anywhere a factor variable appears.
/ is allowed only after anova, cnsreg, manova, mvreg, or regress.
operators (op.) Description
r. differences from the reference (base) level; the default
a. differences from the next level (adjacent contrasts)
ar. differences from the previous level (reverse adjacent contrasts)
As-balanced operators
g.
h.
j.
p.
q.

As-observed operators
gw.
hw.
jw.
pw.
qW.
differences from the balanced grand mean
differences from the balanced mean of subsequent levels (Helmert contrasts)
differences from the balanced mean of previous levels (reverse Helmert contrasts)
orthogonal polynomial in the level values
orthogonal polynomial in the level sequence
differences from the observation-weighted grand mean
differences from the observation-weighted mean of subsequent levels differences from the observation-weighted mean of previous levels observation-weighted orthogonal polynomial in the level values
observation-weighted orthogonal polynomial in the level sequence

One or more individual contrasts may be selected by using the op\#. or op (numlist) . syntax. For example, a3. A selects the adjacent contrast for level 3 of $A$, and $p(1 / 2)$. B selects the linear and quadratic effects of B. Also see Orthogonal polynomial contrasts and Beyond linear models.

## Custom contrasts Description

\{A numlist $\}$
\{A\#B numlist\}
user-defined contrast on the levels of factor A
user-defined contrast on the levels of interaction between A and B
Custom contrasts may be part of a term, such as \{A numlist\}\#B, \{A numlist\}@B, \{A numlist\}|B,\{A\#B numlist $\}$, and \{A numlist \}\#\{B numlist\}. The same is true of higher-order custom contrasts, such as $\{\mathrm{A} \# \mathrm{~B}$ numlist $\} @ C,\{\mathrm{~A} \# \mathrm{~B}$ numlist $\} \# r$. C , and $\{\mathrm{A} \# \mathrm{~B}$ numlist \}\#c.x.

Higher-order interactions with at most eight factor variables are allowed with custom contrasts.

## method

Description
noadjust
bonferroni [adjustall]
sidak [adjustall]
scheffe
do not adjust for multiple comparisons; the default
Bonferroni's method; adjust across all terms
Šidák's method; adjust across all terms
Scheffé's method

## Options

$\qquad$ Main
overall specifies that a joint hypothesis test over all terms be performed.
asobserved specifies that factor covariates be evaluated using the cell frequencies observed in the estimation sample. The default is to treat all factor covariates as though there were an equal number of observations in each level.
lincom specifies that user-defined contrasts be treated as linear combinations. The default is to require that all user-defined contrasts sum to zero. (Summing to zero is part of the definition of a contrast.)

## Equations

equation (eqspec) specifies the equation from which contrasts are to be computed. The default is to compute contrasts from the first equation.
atequations specifies that the contrasts be computed within each equation.

Advanced
emptycells (empspec) specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced.
emptycells(strict) is the default; it specifies that contrasts involving empty cells be treated as not estimable.
emptycells (reweight) specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the contrast estimable but changes its interpretation.
noestimcheck specifies that contrast not check for estimability. By default, the requested contrasts are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If noestimcheck is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations.

## Reporting

level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals. mcompare (method) specifies the method for computing $p$-values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate, $\alpha_{c}$, to achieve a prespecified experimentwise error rate, $\alpha_{e}$.
mcompare(noadjust) is the default; it specifies no adjustment.

$$
\alpha_{c}=\alpha_{e}
$$

mcompare(bonferroni) adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality

$$
\alpha_{e} \leq m \alpha_{c}
$$

where $m$ is the number of comparisons within the term.
The adjusted comparisonwise error rate is

$$
\alpha_{c}=\alpha_{e} / m
$$

mcompare (sidak) adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$
\alpha_{e} \leq 1-\left(1-\alpha_{c}\right)^{m}
$$

where $m$ is the number of comparisons within the term.
The adjusted comparisonwise error rate is

$$
\alpha_{c}=1-\left(1-\alpha_{e}\right)^{1 / m}
$$

This adjustment is exact when the $m$ comparisons are independent.
mcompare (scheffe) controls the experimentwise error rate using the $F$ or $\chi^{2}$ distribution with degrees of freedom equal to the rank of the term.
mcompare (method adjustall) specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in marginslist. This option is compatible only with the bonferroni and sidak methods.
noeffects suppresses the table of individual contrasts with confidence intervals. This table is produced by default when the mcompare() option is specified or when a term in termlist implies all individual contrasts.
cieffects specifies that a table containing a confidence interval for each individual contrast be reported.
pveffects specifies that a table containing a $p$-value for each individual contrast be reported.
effects specifies that a single table containing a confidence interval and $p$-value for each individual contrast be reported.
nowald suppresses the table of Wald tests.
noatlevels indicates that only the overall Wald test be reported for each term containing within or nested (@ or I) operators.
nosvyadjust is for use with svy estimation commands. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is to say the test is carried out as $W / k \sim F(k, d)$ rather than as $(d-k+1) W /(k d) \sim F(k, d-k+1)$, where $k$ is the dimension of the test and $d$ is the total number of sampled PSUs minus the total number of strata. sort specifies that the table of individual contrasts be sorted by the contrast values within each term. post causes contrast to behave like a Stata estimation (e-class) command. contrast posts the vector of estimated contrasts along with the estimated variance-covariance matrix to e(), so you can treat the estimated contrasts just as you would results from any other estimation command. For example, you could use test to perform simultaneous tests of hypotheses on the contrasts, or you could use lincom to create linear combinations.
display_options: vsquish, nofvlabel, fvwrap(\#), fvwrapon(style), cformat(\%fmt), pformat (\%fmt), sformat (\%fmt), and nolstretch.
vsquish specifies that the blank space separating factor-variable terms or time-series-operated variables from other variables in the model be suppressed.
nofvlabel displays factor-variable level values rather than attached value labels. This option overrides the fvlabel setting; see [R] set showbaselevels.
fvwrap(\#) specifies how many lines to allow when long value labels must be wrapped. Labels requiring more than \# lines are truncated. This option overrides the fvwrap setting; see [R] set showbaselevels.
fvwrapon(style) specifies whether value labels that wrap will break at word boundaries or break based on available space.
fvwrapon(word), the default, specifies that value labels break at word boundaries.
fvwrapon(width) specifies that value labels break based on available space.
This option overrides the fvwrapon setting; see [R] set showbaselevels.
cformat (\% firt) specifies how to format contrasts, standard errors, and confidence limits in the table of estimated contrasts.
pformat ( $\% \mathrm{fm} t$ ) specifies how to format $p$-values in the table of estimated contrasts. sformat (\%fmt) specifies how to format test statistics in the table of estimated contrasts. nolstretch specifies that the width of the table of estimated contrasts not be automatically widened to accommodate longer variable names. The default, lstretch, is to automatically widen the table of estimated contrasts up to the width of the Results window. Specifying lstretch or nolstretch overrides the setting given by set lstretch. If set lstretch has not been set, the default is lstretch. nolstretch is not shown in the dialog box.
eform_option specifies that the contrasts table be displayed in exponentiated form. $e^{\text {contrast }}$ is displayed rather than contrast. Standard errors and confidence intervals are also transformed. See $[\mathrm{R}]$ eform_option for the list of available options.

The following option is available with contrast but is not shown in the dialog box:
df (\#) specifies that the $t$ distribution with \# degrees of freedom be used for computing $p$-values and confidence intervals. The default is to use e(df_r) degrees of freedom or the standard normal distribution if e(df_r) is missing.

## Remarks and examples

```
Remarks are presented under the following headings:
Introduction
One-way models
    Estimated cell means
    Testing equality of cell means

## Introduction

contrast performs ANOVA-style tests of main effects, interactions, simple effects, and nested effects. It can easily decompose these tests into constituent contrasts using either named contrasts (codings) or user-specified contrasts. Comparing levels of factor variables-whether as main effects, interactions, or simple effects-is as easy as adding a contrast operator to the variable. The operators can compare each level with the previous level, each level with a reference level, each level with the mean of previous levels, and more.
contrast tests and estimates contrasts. A contrast of the parameters $\mu_{1}, \mu_{2}, \ldots, \mu_{p}$ is a linear combination $\sum_{i} c_{i} \mu_{i}$ whose $c_{i}$ sum to zero. A difference of population means such as $\mu_{1}-\mu_{2}$ is a contrast, as are most other comparisons of population or model quantities (Coster 2005). Some contrasts may be estimated with lincom, but contrast is much more powerful. contrast can handle multiple contrasts simultaneously, and the command's contrast operators make it easy to specify complicated linear combinations.

Both the contrast operation and the creation of the margins for comparison can be performed as though the data were balanced (typical for experimental designs) or using the observed frequencies in the estimation sample (typical for observational studies). contrast can perform these analyses on the results of almost all of Stata's estimators, not just the linear-models estimators.

Most of contrast's computations can be considered comparisons of estimated cell means from a model fit. Tests of interactions are tests of whether the cell means for the interaction are all equal. Tests of main effects are tests of whether the marginal cell means for the factor are all equal. More focused comparisons of cell means (for example, is level 2 equal to level 1) are specified using contrast operators. More formally, all of contrast's computations are comparisons of conditional expectations; cell means are one type of conditional expectation.

All contrasts can also easily be graphed; see [R] marginsplot.
For a discussion of contrasts and testing for linear models, see Searle and Gruber (2017) and Searle (1997). For discussions specifically related to experimental design, see Winer, Brown, and Michels (1991) and Milliken and Johnson (2009). Rosenthal, Rosnow, and Rubin (2000) focus on contrasts with applications in behavioral sciences. Mitchell $(2021,2015)$ and Baldwin (2019) focus on contrasts in Stata.
contrast is a flexible tool for understanding the effects of categorical covariates. If your model contains categorical covariates, and especially if it contains interactions, you will want to use contrast.

## One-way models

Suppose we have collected data on cholesterol levels for individuals from five age groups. To study the effect of age group on cholesterol, we can begin by fitting a one-way model using regress:

```
. use https://www.stata-press.com/data/r18/cholesterol
(Artificial cholesterol data)
. label list ages
ages:
            1 10-19
            2 20-29
            3 30-39
            4 40-59
            5 60-79
```

. regress chol i.agegrp

| Source | SS | df | MS | Number of obs | = | 75 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathrm{F}(4,70)$ | = | 35.02 |

| $20-29$ | 8.203575 | 3.771628 | 2.18 | 0.033 | .6812991 | 15.72585 |
| $30-39$ | 21.54105 | 3.771628 | 5.71 | 0.000 | 14.01878 | 29.06333 |
| $40-59$ | 30.15067 | 3.771628 | 7.99 | 0.000 | 22.6284 | 37.67295 |
| $60-79$ | 38.76221 | 3.771628 | 10.28 | 0.000 | 31.23993 | 46.28448 |
| _cons | 180.5198 | 2.666944 | 67.69 | 0.000 | 175.2007 | 185.8388 |

## Estimated cell means

margins will show us the estimated cell means for each age group based on our fitted model:
. margins agegrp
Adjusted predictions $\quad$ Number of obs $=75$
Model VCE: OLS
Expression: Linear prediction, predict()

|  | Delta-method <br> std. err. |  |  |  |  |  |  |  | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | :---: | :---: | :---: | :---: | :---: |
| agegrp |  |  |  |  |  |  |  |  |  |  |  |
| $10-19$ | 180.5198 | 2.666944 | 67.69 | 0.000 | 175.2007 | 185.8388 |  |  |  |  |  |
| $20-29$ | 188.7233 | 2.666944 | 70.76 | 0.000 | 183.4043 | 194.0424 |  |  |  |  |  |
| $30-39$ | 202.0608 | 2.666944 | 75.76 | 0.000 | 196.7418 | 207.3799 |  |  |  |  |  |
| $40-59$ | 210.6704 | 2.666944 | 78.99 | 0.000 | 205.3514 | 215.9895 |  |  |  |  |  |
| $60-79$ | 219.282 | 2.666944 | 82.22 | 0.000 | 213.9629 | 224.601 |  |  |  |  |  |

We can graph those means with marginsplot:

```
. marginsplot
Variables that uniquely identify margins: agegrp
```

Adjusted predictions of agegrp with $95 \%$ Cls

## Testing equality of cell means

Are all the means equal? That is to say is there an effect of age group on cholesterol level? We can answer that by asking contrast to test whether the means of the age groups are identical.

```
. contrast agegrp
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | $F$ | $P>F$ |
| ---: | ---: | ---: | ---: |
| agegrp | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

The means are clearly different. We could have obtained this same test directly had we fit our model using anova rather than regress.

|  | $\begin{aligned} \text { Number of obs } & = \\ \text { Root MSE } & = \end{aligned}$ | $\begin{array}{r} 75 \\ 10.329 \end{array}$ | R -squared $=$ <br> Adj R-squared $=$ |  | $\begin{aligned} & 0.6668 \\ & 0.6477 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 14943.4 | 4 | 3735.8499 | 35.02 | 0.0000 |
| agegrp | 14943.4 | 4 | 3735.8499 | 35.02 | 0.0000 |
| Residual | 7468.2197 | 70 | 106.68885 |  |  |
| Total | 22411.619 | 74 | 302.85972 |  |  |

Achieving a more direct test result is why we recommend using anova instead of regress for models where our focus is on the categorical covariates. The models fit by anova and regress are identical; they merely parameterize the effects differently. The results of contrast will be identical regardless of which command is used to fit the model. If, however, we were fitting models whose responses are nonlinear functions of the covariates, such as logistic regression, then there would be no analogue to anova, and we would appreciate contrast's ability to quickly test main effects and interactions.

## Reference category contrasts

Now that we know that the overall effect of age group is statistically significant, we can explore the effects of each age group. One way to do that is to use the reference category operator, r.:
. contrast r.agegrp
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| agegrp |  |  |  |
| $(20-29$ vs 10-19) | 1 | 4.73 | 0.0330 |
| $(40-39$ vs 10-19) | 1 | 32.62 | 0.0000 |
| $(60-79$ vs 10-19) vs 10-19) | 1 | 63.91 | 0.0000 |
| Joint | 1 | 105.62 | 0.0000 |
|  | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | :--- | ---: | ---: |
| agegrp |  |  |  |  |
| $(20-29$ vs 10-19) | 8.203575 | 3.771628 | .6812991 | 15.72585 |
| $(30-39$ vs 10-19) | 21.54105 | 3.771628 | 14.01878 | 29.06333 |
| $(40-59$ vs 10-19) | 30.15067 | 3.771628 | 22.6284 | 37.67295 |
| $(60-79$ vs 10-19) | 38.76221 | 3.771628 | 31.23993 | 46.28448 |

The cell mean of each age group is compared against the base age group (ages 10-19). The first table shows that each difference is significant. The second table gives an estimate and confidence interval for each contrast. These are the comparisons that linear regression gives with a factor covariate and no interactions. The contrasts are identical to the coefficients from our linear regression.

## Reverse adjacent contrasts

We have far more flexibility with contrast. Age group is ordinal, so it is interesting to compare each age group with the preceding age group (rather than against one reference group). We specify that analysis by using the reverse adjacent operator, ar.:

| . contrast ar.agegrp |
| :--- |
| Contrasts of marginal linear predictions |
| Margins: asbalanced |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | :--- | :--- | :--- |
| agegrp |  |  |  |  |
| $(20-29$ vs 10-19) | 8.203575 | 3.771628 | .6812991 | 15.72585 |
| $(30-39$ vs 20-29) | 13.33748 | 3.771628 | 5.815204 | 20.85976 |
| $(40-59$ vs $30-39)$ | 8.60962 | 3.771628 | 1.087345 | 16.1319 |
| $(60-79$ vs 40-59) | 8.611533 | 3.771628 | 1.089257 | 16.13381 |

The 20-29 age group's cholesterol level is 8.2 points higher than the $10-19$ age group's cholesterol level; the $30-39$ age group's level is 13.3 points higher than the $20-29$ age group's level; and so on. Each age group is statistically different from the preceding age group at the $5 \%$ level.

## Orthogonal polynomial contrasts

The relationship between age group and cholesterol level looked almost linear in our graph. We can examine that relationship further by using the orthogonal polynomial operator, p.:

```
. contrast p.agegrp, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | ---: | ---: |
| agegrp |  |  |  |
| (linear) | 1 | 139.11 | 0.0000 |
| (quadratic) | 1 | 0.15 | 0.6962 |
| (quartic) | 1 | 0.37 | 0.5448 |
| Joint | 1 | 0.43 | 0.5153 |
| Denominator | 4 | 35.02 | 0.0000 |

Only the linear effect is statistically significant.
We can even perform the joint test that all effects beyond linear are zero. We do that by selecting all polynomial contrasts above linear-that is, polynomial contrasts 2, 3, and 4.

```
. contrast p(2 3 4).agegrp, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | :---: | :---: |
| agegrp |  |  |  |
| (quadratic) | 1 | 0.15 | 0.6962 |
| (cubic) | 1 | 0.37 | 0.5448 |
| (quartic) | 1 | 0.43 | 0.5153 |
| Joint | 3 | 0.32 | 0.8129 |
| Denominator | 70 |  |  |

The joint test has three degrees of freedom and is clearly insignificant. A linear effect of age group seems adequate for this model.

## Two-way models

Suppose we are investigating the effects of different dosages of a blood pressure medication and believe that the effects may be different for men and women. We can fit the following ANOVA model for bpchange, the change in diastolic blood pressure. Change is defined as the after measurement minus the before measurement, so that negative values of bpchange correspond to decreases in blood pressure.

| (Artificial blood pr <br> . label list gender gender: |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 Male <br> 2 Female |  |  |  |  |  |
| anova bpchange dose\#\#gender |  |  |  |  |  |
|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | 30 | R -squared = |  | 0.9647 |
|  |  | 1.4677 | Adj R- | uared = | 0.9573 |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 1411.9087 | 52 | 282.38174 | 131.09 | 0.0000 |
| dose | 963.48179 | 2 | 481.7409 | 223.64 | 0.0000 |
| gender | 355.11882 | 1 | 355.11882 | 164.85 | 0.0000 |
| dose\#gender | 93.308093 | 2 | 46.654046 | 21.66 | 0.0000 |
| Residual | 51.699253 | $24 \quad 2$ | 2.1541355 |  |  |
| Total | 1463.608 | 29 | 50.46924 |  |  |

## Estimated interaction cell means

Everything is significant, including the interaction. So increasing dosage is effective and differs by gender. Let's explore the effects. First, let's look at the estimated cell mean of blood pressure change for each combination of gender and dosage.

| Adjusted predictions |  |  |  |  | Number of obs $=30$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Expression: Linear prediction, predict() |  |  |  |  |  |  |
|  | Delta-method |  |  | $P>\|t\|$ | [95\% conf. interval] |  |
| dose\#gender 250\#Male | -7.35384 | . 6563742 | -11.20 | 0.000 | -8.708529 | -5.99915 |
| 250\#Female | 3.706567 | . 6563742 | 5.65 | 0.000 | 2.351877 | 5.061257 |
| 500\#Male | -13.73386 | . 6563742 | -20.92 | 0.000 | -15.08855 | -12.37917 |
| 500\#Female | -6.584167 | . 6563742 | -10.03 | 0.000 | -7.938857 | -5.229477 |
| 750\#Male | -16.82108 | . 6563742 | -25.63 | 0.000 | -18.17576 | -15.46639 |
| 750\#Female | -14.38795 | . 6563742 | -21.92 | 0.000 | -15.74264 | -13.03326 |

Our data are balanced, so these results will not be affected by the many different ways that margins can compute cell means. Moreover, because our model consists of only dose and gender, these are also the point estimates for each combination.

We can graph the results:

```
. marginsplot
Variables that uniquely identify margins: dose gender
```

The lines are not parallel, which we expected because the interaction term is significant. Males experience a greater decline in blood pressure at every dosage level, but the effect of increasing dosage is greater for females. In fact, it is not clear if we can tell the difference between male and female response at the maximum dosage.

## Simple effects

We can contrast the male and female responses within dosage to see the simple effects of gender. Because there are only two levels in gender, the choice of contrast operator is largely irrelevant. Aside from orthogonal polynomials, all operators produce the same estimates, although the effects can change signs.

- contrast r.gender@dose

Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| gender@dose |  |  |  |
| (Female vs Male) 250 | 1 | 141.97 | 0.0000 |
| (Female vs Male) 500 | 1 | 59.33 | 0.0000 |
| (Female vs Male) 750 | 1 | 6.87 | 0.0150 |
| Joint | 3 | 69.39 | 0.0000 |
| Denominator | 24 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: |
| gender@dose |  |  |  |  |
| (Female vs Male) 250 | 11.06041 | .9282533 | 9.144586 | 12.97623 |
| (Female vs Male) 500 | 7.149691 | .9282533 | 5.23387 | 9.065512 |
| (Female vs Male) 750 | 2.433124 | .9282533 | .5173031 | 4.348944 |

The effect for females is about 11 points higher than for males at a dosage of 250, and that shrinks to 2.4 points higher at the maximum dosage of 750 .

We can form the simple effects the other way by contrasting the effect of dose at each level of gender:
. contrast ar.dose@gender
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| dose@gender |  |  |  |
| (500 vs 250) Male | 1 | 47.24 | 0.0000 |
| $(500$ vs 250) Female | 1 | 122.90 | 0.0000 |
| (750 vs 500) Male | 1 | 11.06 | 0.0028 |
| $(750$ vs 500) Female | 1 | 70.68 | 0.0000 |
| Joint | 4 | 122.65 | 0.0000 |
| Denominator |  |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: |
| dose@gender |  |  |  |  |
| (500 vs 250) Male | -6.380018 | .9282533 | -8.295839 | -4.464198 |
| (500 vs 250) Female | -10.29073 | .9282533 | -12.20655 | -8.374914 |
| (750 vs 500) Male | -3.087217 | .9282533 | -5.003038 | -1.171396 |
| $(750$ vs 500) Female | -7.803784 | .9282533 | -9.719605 | -5.887963 |

Here we use the ar. reverse adjacent contrast operator so that first we are comparing a dosage of 500 with a dosage of 250 , and then we are comparing 750 with 500 . We see that increasing the dosage has a larger effect on females- 10.3 points when going from 250 to 500 compared with 6.4 points for males, and 7.8 points when going from 500 to 750 versus 3.1 points for males.

## Interaction effects

By specifying contrast operators on both factors, we can decompose the interaction effect into separate interaction contrasts.
. contrast ar.dose\#r.gender
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | :---: | :---: |
| dose\#gender |  |  |  |
| (500 vs 250) (Female vs Male) | 1 | 8.87 | 0.0065 |
| (750 vs 500) (Female vs Male) | 1 | 12.91 | 0.0015 |
| Joint | 2 | 21.66 | 0.0000 |
| Denominator | 24 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| ---: | :---: | :---: | :---: | :---: |
| dose\#gender <br> $(500$ vs 250) |  |  |  |  |
| $\left(\begin{array}{r}\text { Female vs Male) } \\ (750 \text { vs 500) }\end{array}\right.$ | -3.910716 | 1.312748 | -6.620095 | -1.201336 |
| $($ Female vs Male) | -4.716567 | 1.312748 | -7.425947 | -2.007187 |

Look for departures from zero to indicate an interaction effect between dose and gender. Both contrasts are significantly different from zero. Of course, we already knew the overall interaction was significant from our ANOVA results. The effect of increasing dose from 250 to 500 is 3.9 points greater in females than in males, and the effect of increasing dose from 500 to 750 is 4.7 points greater in females than in males. The confidence intervals for both estimates easily exclude zero, meaning that there is an interaction effect.

The joint test of these two interaction effects reproduces the test of interaction effects in the anova output. We can see that the $F$ statistic of 21.66 matches the statistic from our original ANOVA results.

## Main effects

We can perform tests of the main effects by listing each variable individually in contrast.

```
. contrast dose gender
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | $F$ | $P>F$ |
| ---: | ---: | ---: | ---: |
| dose | 2 | 223.64 | 0.0000 |
| gender | 1 | 164.85 | 0.0000 |
| Denominator | 24 |  |  |

The $F$ tests are equivalent to the tests of main effects in the anova output. This is true only for linear models. contrast provides an easy way to obtain main effects and other ANOVA-style tests for models whose responses are not linear in the parameters-logistic, probit, glm, etc.

If we include contrast operators on the variables, we can also decompose the main effects into individual contrasts:
. contrast ar.dose r.gender
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| dose |  |  |  |
| (500 vs 250) | 1 | 161.27 | 0.0000 |
| $(750$ vs 500) | 1 | 68.83 | 0.0000 |
| Joint | 2 | 223.64 | 0.0000 |
| gender | 1 | 164.85 | 0.0000 |
| Denominator | 24 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | :--- | ---: | ---: |
| dose |  |  |  |  |
| $(500$ vs 250) | -8.335376 | .6563742 | -9.690066 | -6.980687 |
| $(750$ vs 500) | -5.4455 | .6563742 | -6.80019 | -4.090811 |
| gender |  |  |  |  |

By specifying the ar. operator on dose, we decompose the main effect for dose into two one-degree-of-freedom contrasts, comparing the marginal mean of blood pressure change for each dosage level with that of the previous level. Because gender has only two levels, we cannot decompose this main effect any further. However, specifying a contrast operator on gender allowed us to calculate the difference in the marginal means for women and men.

## Partial interaction effects

At this point, we have looked at the total interaction effects and at the main effects of each variable. The partial interaction effects are a midpoint between these two types of effects where we collect the individual interaction effects along the levels of one of the variables and perform a joint test of those interactions. If we think of the interaction effects as forming a table, with the levels of one factor variable forming the rows and the levels of the other forming the columns, partial interaction effects are joint tests of the interactions in a row or a column. To perform these tests, we specify a contrast operator on only one of the variables in our interaction. For this particular model, these are not very interesting because our variables have only two and three levels. Therefore, the tests of the partial interaction effects reproduce the tests that we obtained for the total interaction effects. We specify a contrast operator only on dose to decompose the overall test for interaction effects into joint tests for each ar.dose contrast:

```
. contrast ar.dose#gender
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| dose\#gender |  |  |  |
| $(500$ vs 250) (joint) | 1 | 8.87 | 0.0065 |
| $(750$ vs 500) (joint) | 1 | 12.91 | 0.0015 |
| Joint | 2 | 21.66 | 0.0000 |
| Denominator | 24 |  |  |

The first row is a joint test of all the interaction effects involving the ( 500 vs 250 ) comparison of dosages. The second row is a joint test of all the interaction effects involving the ( 750 vs 500 ) comparison. If we look back at our output in Interaction effects, we can see that there was only one of each of these interaction effects. Therefore, each test labeled (joint) has only one degree-of-freedom.

We could have instead included a contrast operator on gender to compute the partial interaction effects along the other dimension:

```
. contrast dose#r.gender
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :--- | :---: | :---: | ---: |
| dose\#gender | 2 | 21.66 | 0.0000 |
| Denominator | 24 |  |  |

Here we obtain a joint test of all the interaction effects involving the (Female vs Male) comparison for gender. Because gender has only two levels, the (Female vs Male) contrast is the only reference category contrast possible. Therefore, we obtain a single joint test of all the interaction effects.

Clearly, the partial interaction effects are not interesting for this particular model. However, if our factors had more levels, the partial interaction effects would produce tests that are not available in the total interaction effects. For example, if our model included factors for four dosage levels and three races, then typing
. contrast ar.dose\#race
would produce three joint tests, one for each of the reverse adjacent contrasts for dosage. Each of these tests would be a two-degree-of-freedom test because race has three levels.

## Three-way and higher-order models

All the contrasts and tests that we reviewed above for two-way models can be used with models that have more terms. For instance, we could fit a three-way full factorial model by using the anova command:

```
. use https://www.stata-press.com/data/r18/cont3way
. anova y race##sex##group
```

We could then test the simple effects of race within each level of the interaction between sex and group:

```
. contrast race@sex#group
```

To see the reference category contrasts that decompose these simple effects, type

```
. contrast r.race@sex#group
```

We could test the three-way interaction effects by typing

```
. contrast race#sex#group
```

or the interaction effects for the interaction of race and sex by typing

```
. contrast race#sex
```

To see the individual reference category contrasts that decompose this interaction effect, type

```
. contrast r.race#r.sex
```

We could even obtain joint tests for the interaction of race and sex within each level of group by typing

For tests of the main effects of each factor, we can type

```
. contrast race sex group
```

We can calculate the individual reference category contrasts that decompose these main effects:

```
. contrast r.race r.sex r.group
```

For the partial interaction effects, we could type

```
. contrast r.race#group
```

to obtain a joint test of the two-way interaction effects of race and group for each of the individual r.race contrasts.

We could type
. contrast r.race\#sex\#group
to obtain a joint test of all the three-way interaction terms for each of the individual r.race contrasts.

## Contrast operators

contrast recognizes a set of contrast operators that are used to specify commonly used contrasts. When these operators are used, contrast will report a test for each individual contrast in addition to the joint test for the term. We have already seen a few of these, like r. and ar., in the previous examples. Here we will take a closer look at each of the unweighted operators.

Here we use the cholesterol dataset and the one-way ANOVA model from the example in One-way models:

```
. use https://www.stata-press.com/data/r18/cholesterol
(Artificial cholesterol data)
. anova chol agegrp
    (output omitted)
```

The margins command reports the estimated cell means, $\widehat{\mu}_{1}, \ldots, \widehat{\mu}_{5}$, for each of the five age groups.

```
. margins agegrp
Adjusted predictions Number of obs = 75
Expression: Linear prediction, predict()
```

|  | Delta-method <br> std. err. |  |  |  | t | $\mathrm{P}>\|\mathrm{t}\|$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Margin | [95\% conf. interval] |  |  |  |  |
| agegrp |  |  |  |  |  |  |
| $10-19$ | 180.5198 | 2.666944 | 67.69 | 0.000 | 175.2007 | 185.8388 |
| $20-29$ | 188.7233 | 2.666944 | 70.76 | 0.000 | 183.4043 | 194.0424 |
| $30-39$ | 202.0608 | 2.666944 | 75.76 | 0.000 | 196.7418 | 207.3799 |
| $40-59$ | 210.6704 | 2.666944 | 78.99 | 0.000 | 205.3514 | 215.9895 |
| $60-79$ | 219.282 | 2.666944 | 82.22 | 0.000 | 213.9629 | 224.601 |

Contrast operators provide an easy way to make certain types of comparisons of these cell means. We use the ordinal factor agegrp to demonstrate these operators because some types of contrasts are meaningful only when the levels of the factor have a natural ordering. We demonstrate these contrast operators using a one-way model; however, they are equally applicable to main effects, simple effects, and interactions for more complicated models.

## Differences from a reference level (r.)

The r. operator specifies that each level of the attached factor variable be compared with a reference level. These are referred to as reference-level or reference-category contrasts (or effects), and $r$. is the reference-level operator.

In the following, we use the r. operator to test the effect of each category of age group when that category is compared with a reference category.

```
. contrast r.agegrp
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| agegrp |  |  |  |
| $(20-29$ vs 10-19) | 1 | 4.73 | 0.0330 |
| $(40-39$ vs 10-19) | 1 | 32.62 | 0.0000 |
| $(60-79$ vs 10-19) | 1 | 63.91 | 0.0000 |
| Jo-19) | 1 | 105.62 | 0.0000 |
| Joint | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | :--- | ---: | ---: |
| agegrp |  |  |  |  |
| $(20-29$ vs 10-19) | 8.203575 | 3.771628 | .6812991 | 15.72585 |
| $(30-39$ vs 10-19) | 21.54105 | 3.771628 | 14.01878 | 29.06333 |
| $(40-59$ vs 10-19) | 30.15067 | 3.771628 | 22.6284 | 37.67295 |
| $(60-79$ vs 10-19) | 38.76221 | 3.771628 | 31.23993 | 46.28448 |

In the first table, the row labeled (20-29 vs $10-19$ ) is a test of $\mu_{2}=\mu_{1}$, a test that the mean cholesterol levels for the $10-19$ age group and the $20-29$ age group are equal. The tests in the next three rows are defined similarly. The row labeled Joint provides the joint test for these four hypotheses, which is just the test of the main effects of age group.

The second table provides the contrasts of each category with the reference category along with confidence intervals. The contrast in the row labeled (20-29 vs 10-19) is the difference in the cell means of the second age group and the first age group, $\widehat{\mu}_{2}-\widehat{\mu}_{1}$.

The first level of a factor is the default reference level, but we can specify a different reference level by using the b . operator; see [U] 11.4.3.2 Base levels. Here we use the last age group, (60-79), instead of the first as the reference category. We also include the nowald option so that only the table of contrasts and their confidence intervals is produced.

```
. contrast rb5.agegrp, nowald
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | :--- | :--- | :--- | :--- |
| agegrp |  |  |  |  |
| $(10-19$ vs 60-79) | -38.76221 | 3.771628 | -46.28448 | -31.23993 |
| $(20-29$ vs 60-79) | -30.55863 | 3.771628 | -38.08091 | -23.03636 |
| $(30-39$ vs 60-79) | -17.22115 | 3.771628 | -24.74343 | -9.698877 |
| $(40-59$ vs $60-79)$ | -8.611533 | 3.771628 | -16.13381 | -1.089257 |

Now, the first row is labeled ( $10-19$ vs $60-79$ ) and is the difference in the cell means of the first and fifth age groups.

## Differences from the next level (a.)

The a. operator specifies that each level of the attached factor variable be compared with the next level. These are referred to as adjacent contrasts (or effects), and a. is the adjacent operator. This operator is meaningful only with factor variables that have a natural ordering in the levels.

We can use the a. operator to perform tests that each level of age group differs from the next adjacent level.

```
. contrast a.agegrp
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| agegrp |  |  |  |
| $(10-19$ vs 20-29) | 1 | 4.73 | 0.0330 |
| $(20-29$ vs 30-39) | 1 | 12.51 | 0.0007 |
| $(40-39$ vs 40-59) | 1 | 5.21 | 0.0255 |
| vs 60-79) | 1 | 5.21 | 0.0255 |
| Joint | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | :--- | ---: | ---: |
| agegrp |  |  |  |  |
| $(10-19$ vs 20-29) | -8.203575 | 3.771628 | -15.72585 | -.6812991 |
| $(20-29$ vs 30-39) | -13.33748 | 3.771628 | -20.85976 | -5.815204 |
| $(30-39$ vs 40-59) | -8.60962 | 3.771628 | -16.1319 | -1.087345 |
| $(40-59$ vs 60-79) | -8.611533 | 3.771628 | -16.13381 | -1.089257 |

In the first table, the row labeled (10-19 vs 20-29) tests the effect of belonging to the $10-19$ age group instead of the 20-29 age group. Likewise, the rows labeled ( $20-29$ vs 30-39), (30-39 vs 4059 ), and ( $40-59$ vs $60-79$ ) are tests for the effects of being in the younger of the two age groups instead of the older one.

In the second table, the contrast in the row labeled ( $10-19$ vs $20-29$ ) is the difference in the cell means of the first and second age groups, $\widehat{\mu}_{1}-\widehat{\mu}_{2}$. The contrasts in the other rows are defined similarly.

## Differences from the previous level (ar.)

The ar. operator specifies that each level of the attached factor variable be compared with the previous level. These are referred to as reverse adjacent contrasts (or effects), and ar. is the reverse adjacent operator. As with the a. operator, this operator is meaningful only with factor variables that have a natural ordering in the levels.

In the following, we use the ar. operator to report tests for the individual reverse adjacent effects of agegrp.

Here the Wald tests in the first table for the individual reverse adjacent effects are equivalent to the tests for the adjacent effects in the previous example. However, if we compare values of the contrasts in the bottom tables, we see the difference between the r. and the ar. operators. This time, the contrast in the first row is labeled (20-29 vs 10-19) and is the difference in the cell means of the second and first age groups, $\widehat{\mu}_{2}-\widehat{\mu}_{1}$. This is the estimated effect of belonging to the 20-29 age group instead of the 10-19 age group. The remaining rows make similar comparisons with the previous level.

## Differences from the grand mean (g.)

The $g$. operator specifies that each level of a factor variable be compared with the grand mean of all levels. For this operator, the grand mean is computed using a simple average of the cell means.

Here are the grand mean effects of agegrp:

```
. contrast g.agegrp
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | $F$ | $P>F$ |
| :---: | :---: | ---: | ---: |
| $(10-19$ vs mean) | 1 | 68.42 | 0.0000 |
| $(20-29$ vs mean) | 1 | 23.36 | 0.0000 |
| $(30-39$ vs mean) | 1 | 0.58 | 0.4506 |
| $(40-59$ vs mean) | 1 | 19.08 | 0.0000 |
| $(60-79$ vs mean) | 1 | 63.65 | 0.0000 |
| Joint | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | :--- | ---: | ---: |
| agegrp |  |  |  |  |
| $(10-19$ vs mean) | -19.7315 | 2.385387 | -24.48901 | -14.974 |
| $(20-29$ vs mean) | -11.52793 | 2.385387 | -16.28543 | -6.770423 |
| $(30-39$ vs mean) | 1.809552 | 2.385387 | -2.947953 | 6.567057 |
| $(40-59$ vs mean) | 10.41917 | 2.385387 | 5.661668 | 15.17668 |
| $(60-79$ vs mean) | 19.0307 | 2.385387 | 14.2732 | 23.78821 |

There are five age groups in our estimation sample. Thus, the row labeled (10-19 vs mean) tests $\mu_{1}=$ $\left(\mu_{1}+\mu_{2}+\mu_{3}+\mu_{4}+\mu_{5}\right) / 5$. The row labeled (20-29 vs mean) tests $\mu_{2}=\left(\mu_{1}+\mu_{2}+\mu_{3}+\mu_{4}+\mu_{5}\right) / 5$. The remaining rows perform similar tests for the third, fourth, and fifth age groups. In our example, the means for all age groups except the $30-39$ age group are statistically different from the grand mean.

## Differences from the mean of subsequent levels (h.)

The $h$. operator specifies that each level of the attached factor variable be compared with the mean of subsequent levels. These are referred to as Helmert contrasts (or effects), and h. is the Helmert operator. For this operator, the mean is computed using a simple average of the cell means. This operator is meaningful only with factor variables that have a natural ordering in the levels.

Here are the Helmert contrasts for agegrp:

```
. contrast h.agegrp
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| agegrp |  |  |  |
| $(10-19$ vs >10-19) | 1 | 68.42 | 0.0000 |
| $(20-29$ vs >20-29) | 1 | 50.79 | 0.0000 |
| $(30-39$ vs >30-39) | 1 | 15.63 | 0.0002 |
| $(40-59$ vs $60-79)$ | 1 | 5.21 | 0.0255 |
| Joint | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | :--- | :--- | :--- | :--- |
| agegrp |  |  |  |  |
| $(10-19$ vs >10-19) | -24.66438 | 2.981734 | -30.61126 | -18.7175 |
| $(20-29$ vs >20-29) | -21.94774 | 3.079522 | -28.08965 | -15.80583 |
| $(30-39$ vs >30-39) | -12.91539 | 3.266326 | -19.42987 | -6.400905 |
| $(40-59$ vs $60-79)$ | -8.611533 | 3.771628 | -16.13381 | -1.089257 |

The row labeled (10-19 vs >10-19) tests $\mu_{1}=\left(\mu_{2}+\mu_{3}+\mu_{4}+\mu_{5}\right) / 4$, that is, that the cell mean for the youngest age group is equal to the average of the cell means for the older age groups. The row labeled (20-29 vs >20-29) tests $\mu_{2}=\left(\mu_{3}+\mu_{4}+\mu_{5}\right) / 3$. The tests in the other rows are defined similarly.

## Differences from the mean of previous levels (j.)

The $j$. operator specifies that each level of the attached factor variable be compared with the mean of the previous levels. These are referred to as reverse Helmert contrasts (or effects), and $j$. is the reverse Helmert operator. For this operator, the mean is computed using a simple average of the cell means. This operator is meaningful only with factor variables that have a natural ordering in the levels.

Here are the reverse Helmert contrasts of agegrp:

```
. contrast j.agegrp
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | :---: | :---: |
| agegrp |  |  |  |
| (20-29 vs 10-19) | 1 | 4.73 | 0.0330 |
| (30-39 vs <30-39) | 1 | 28.51 | 0.0000 |
| (40-59 vs <40-59) | 1 | 43.18 | 0.0000 |
| (60-79 vs <60-79) | 1 | 63.65 | 0.0000 |
| Joint | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | :--- | ---: | ---: |
| agegrp |  |  |  |  |
| $(20-29$ vs 10-19) | 8.203575 | 3.771628 | .6812991 | 15.72585 |
| $(30-39$ vs <30-39) | 17.43927 | 3.266326 | 10.92479 | 23.95375 |
| $(40-59$ vs <40-59) | 20.2358 | 3.079522 | 14.09389 | 26.37771 |
| $(60-79$ vs <60-79) | 23.78838 | 2.981734 | 17.8415 | 29.73526 |

The row labeled (20-29 vs $10-19$ ) tests $\mu_{2}=\mu_{1}$, that is, that the cell means for the $20-29$ and the $10-19$ age groups are equal. The row labeled (30-39 vs <30-29) tests $\mu_{3}=\left(\mu_{1}+\mu_{2}\right) / 2$, that is, that the cell mean for the $30-39$ age group is equal to the average of the cell means for the $10-19$ and $20-29$ age groups. The tests in the remaining rows are defined similarly.

## Orthogonal polynomials (p. and q.)

The p. and q. operators specify that orthogonal polynomials be applied to the attached factor variable. Orthogonal polynomial contrasts allow us to partition the effects of a factor variable into linear, quadratic, cubic, and higher-order polynomial components. The p. operator applies orthogonal polynomials using the values of the factor variable. The $q$. operator applies orthogonal polynomials using the level indices. If the level values of the factor variable are equally spaced, as with our agegrp variable, then the p. and q. operators yield the same result. These operators are meaningful only with factor variables that have a natural ordering in the levels.

Because agegrp has five levels, contrast can test the linear, quadratic, cubic, and quartic effects of agegrp.

```
. contrast p.agegrp, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | ---: | ---: | ---: |
| agegrp |  |  |  |
| (linear) | 1 | 139.11 | 0.0000 |
| (quadratic) | 1 | 0.15 | 0.6962 |
| (cubic) | 1 | 0.37 | 0.5448 |
| (quartic) | 1 | 0.43 | 0.5153 |
| Joint | 4 | 35.02 | 0.0000 |
|  |  |  |  |
| Denominator | 70 |  |  |

The row labeled (linear) tests the linear effect of agegrp, the only effect that appears to be significant in this case.

The labels for our agegrp variable show the age ranges that correspond to each level.

```
. label list ages
ages:
    1 10-19
    2 20-29
    3 30-39
    4 40-59
    5 60-79
```

Notice that these groups do not have equal widths. Now, let's refit our model using the agemidpt variable. The values of agemidpt indicate the midpoint of each age group that was defined by the agegrp variable and are, therefore, not equally spaced.
. anova chol agemidpt

|  | $\begin{aligned} \text { Number of obs } & = \\ \text { Root MSE } & = \end{aligned}$ | 10.3 | R -squared |  | $\begin{aligned} & 0.6668 \\ & 0.6477 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 14943.4 | 4 | 3735.8499 | 35.02 | 0.0000 |
| agemidpt | 14943.4 | 4 | 3735.8499 | 35.02 | 0.0000 |
| Residual | 7468.2197 | 70 | 106.68885 |  |  |
| Total | 22411.619 | 74 | 302.85972 |  |  |

Now if we use the q. operator, we will obtain the same results as above because the level indices of agemidpt are equivalent to the values of agegrp.

```
. contrast q.agemidpt, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | ---: | ---: | ---: |
| agemidpt |  |  |  |
| (linear) | 1 | 139.11 | 0.0000 |
| (quadratic) | 1 | 0.15 | 0.6962 |
| (cubic) | 1 | 0.37 | 0.5448 |
| (quartic) | 1 | 0.43 | 0.5153 |
| Joint | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

However, if we use the p. operator, we will instead fit an orthogonal polynomial to the midpoint values.

```
. contrast p.agemidpt, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | ---: | ---: |
| agemidpt |  |  |  |
| (linear) | 1 | 133.45 | 0.0000 |
| (quadratic) | 1 | 5.40 | 0.0230 |
| (cubic) | 1 | 0.05 | 0.8198 |
| (quartic) | 1 | 1.16 | 0.2850 |
| Joint | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

Using the values of the midpoints, the quadratic effect is also significant at the $5 \%$ level.

## - Technical note

We used the noeffects option when working with orthogonal polynomial contrasts. Apart from perhaps the sign of the contrast, the values of the individual contrasts are not meaningful for orthogonal polynomial contrasts. In addition, many textbooks provide tables with contrast coefficients that can be used to compute orthogonal polynomial contrasts where the levels of a factor are equally spaced. If
we use these coefficients and calculate the contrasts manually with user-defined contrasts, as described below, the Wald tests for the polynomial terms will be equivalent, but the values of the individual contrasts will not necessarily match those that we obtain when using the polynomial contrast operator. When we use one of these contrast operators, an algorithm is used to calculate the coefficients of the polynomial contrast that will allow for unequal spacing in the levels of the factor as well as in the weights for the cell frequencies (when using pw. or qw.), as described in Methods and formulas.

## User-defined contrasts

In the previous examples, we performed tests using contrast operators. When there is not a contrast operator available to calculate the contrast in which we are interested, we can specify custom contrasts.

Here we fit a one-way model for cholesterol on the factor race, which has three levels:

margins calculates the estimated cell mean cholesterol level for each race:
. margins race
Adjusted predictions $\quad$ Number of obs $=75$
Expression: Linear prediction, predict()

|  | MarginDelta-method <br> std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| race |  |  |  |  |  |  |
| Black | 204.4279 | 3.475497 | 58.82 | 0.000 | 197.4996 | 211.3562 |
| White | 197.6132 | 3.475497 | 56.86 | 0.000 | 190.6849 | 204.5415 |
| Other | 198.7127 | 3.475497 | 57.18 | 0.000 | 191.7844 | 205.6409 |

Suppose we want to test the following linear combination:

$$
\sum_{i=1}^{3} c_{i} \mu_{i}
$$

where $\mu_{i}$ is the cell mean of chol when race is equal to its $i$ th level (the means estimated using margins above). Assuming the $c_{i}$ elements sum to zero, this linear combination is a contrast. We can specify this type of custom contrast by using the following syntax:

$$
\left\{\text { race } c_{1} c_{2} c_{3}\right\}
$$

The null hypothesis for the test of the main effects of race is

$$
H_{0_{\text {race }}}: \mu_{1}=\mu_{2}=\mu_{3}
$$

Although $H_{0_{\text {race }}}$ can be tested using any of several different contrasts on the cell means, we will test it by comparing the second and third cell means with the first. To test that the cell means for blacks and whites are equal, $\mu_{1}=\mu_{2}$, we can specify the contrast

$$
\{\text { race -1 } 100\}
$$

To test that the cell means for blacks and other races are equal, $\mu_{1}=\mu_{3}$, we can specify the contrast

$$
\{\text { race }-101\}
$$

We can use both in a single call to contrast.
. contrast \{race -110$\}$ \{race -101$\}$
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| race |  |  |  |
| (1) | 1 | 1.92 | 0.1699 |
| (2) | 1 | 1.35 | 0.2488 |
| Joint | 2 | 1.11 | 0.3357 |
| Denominator | 72 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | :--- | :--- | :--- | :--- |
| race |  |  |  |  |
| $(1)$ | -6.814717 | 4.915095 | -16.61278 | 2.983345 |
| $(2)$ | -5.715261 | 4.915095 | -15.51332 | 4.082801 |

The row labeled (1) is the test for $\mu_{1}=\mu_{2}$, the first specified contrast. The row labeled (2) is the test for $\mu_{1}=\mu_{3}$, the second specified contrast. The row labeled Joint is the overall test for the main effects of race.

Now, let's fit a model with two factors, race and age group:
. anova chol race\#\#agegrp

|  | $\begin{aligned} \text { Number of obs } & = \\ \text { Root MSE } & = \end{aligned}$ | $\begin{array}{r} 75 \\ 9.61785 \end{array}$ | R-squared |  | $\begin{aligned} & 0.7524 \\ & 0.6946 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 16861.438 | 14 | 1204.3884 | 13.02 | 0.0000 |
| race | 669.27823 | 2 | 334.63912 | 3.62 | 0.0329 |
| agegrp | 14943.4 | 4 | 3735.8499 | 40.39 | 0.0000 |
| race\#agegrp | 1248.7601 | 8 | 156.09501 | 1.69 | 0.1201 |
| Residual | 5550.1814 | 60 | 92.503024 |  |  |
| Total | 22411.619 | 74 | 302.85972 |  |  |

The null hypothesis for the test of the main effects of race is now

$$
H_{0_{\text {race }}}: \mu_{1}=\mu_{2}=\mu_{3} .
$$

where $\mu_{i}$. is the marginal mean of chol when race is equal to its $i$ th level.
We can use the same syntax as above to perform this test by specifying contrasts on the marginal means of race:

```
. contrast {race -1 1 0} {race -1 0 1}
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| race |  |  |  |
| $(1)$ | 1 | 6.28 | 0.0150 |
| (2) | 1 | 4.41 | 0.0399 |
| Joint | 2 | 3.62 | 0.0329 |
| Denominator | 60 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | :--- | ---: | ---: |
| race |  |  |  |  |
| $(1)$ | -6.814717 | 2.720339 | -12.2562 | -1.37323 |
| $(2)$ | -5.715261 | 2.720339 | -11.15675 | -.2737739 |

Custom contrasts may be specified on the cell means of interactions, too. Here we use margins to calculate the mean of chol for each cell in the interaction of race and agegrp:
. margins race\#agegrp
Adjusted predictions $\quad$ Number of obs $=75$
Expression: Linear prediction, predict()

|  | Delta-method |  | t | $P>\|t\|$ | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| race\#agegrp |  |  |  |  |  |  |
| Black\#10-19 | 179.2309 | 4.301233 | 41.67 | 0.000 | 170.6271 | 187.8346 |
| Black\#20-29 | 196.4777 | 4.301233 | 45.68 | 0.000 | 187.874 | 205.0814 |
| Black\#30-39 | 210.6694 | 4.301233 | 48.98 | 0.000 | 202.0656 | 219.2731 |
| Black\#40-59 | 214.097 | 4.301233 | 49.78 | 0.000 | 205.4933 | 222.7008 |
| Black\#60-79 | 221.6646 | 4.301233 | 51.54 | 0.000 | 213.0609 | 230.2684 |
| White\#10-19 | 186.0727 | 4.301233 | 43.26 | 0.000 | 177.469 | 194.6765 |
| White\#20-29 | 184.6714 | 4.301233 | 42.93 | 0.000 | 176.0676 | 193.2751 |
| White\#30-39 | 196.2633 | 4.301233 | 45.63 | 0.000 | 187.6595 | 204.867 |
| White\#40-59 | 209.9953 | 4.301233 | 48.82 | 0.000 | 201.3916 | 218.5991 |
| White\#60-79 | 211.0633 | 4.301233 | 49.07 | 0.000 | 202.4595 | 219.667 |
| Other\#10-19 | 176.2556 | 4.301233 | 40.98 | 0.000 | 167.6519 | 184.8594 |
| Other\#20-29 | 185.0209 | 4.301233 | 43.02 | 0.000 | 176.4172 | 193.6247 |
| Other\#30-39 | 199.2498 | 4.301233 | 46.32 | 0.000 | 190.646 | 207.8535 |
| Other\#40-59 | 207.9189 | 4.301233 | 48.34 | 0.000 | 199.3152 | 216.5227 |
| Other\#60-79 | 225.118 | 4.301233 | 52.34 | 0.000 | 216.5143 | 233.7218 |

Now, we are interested in testing the following linear combination of these cell means:

$$
\sum_{i=1}^{3} \sum_{j=1}^{5} c_{i j} \mu_{i j}
$$

We can specify this type of custom contrast using the following syntax:

$$
\left\{\text { race\#agegrp } c_{11} c_{12} \ldots c_{15} c_{21} c_{22} \ldots c_{25} c_{31} c_{32} \ldots c_{35}\right\}
$$

Because the marginal means of chol for each level of race are linear combinations of the cell means, we can compose the test for the main effects of race in terms of the cell means directly. The constraint that the marginal means for blacks and whites are equal, $\mu_{1} .=\mu_{2}$., translates to the following constraint on the cell means:

$$
\frac{1}{5}\left(\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}\right)=\frac{1}{5}\left(\mu_{21}+\mu_{22}+\mu_{23}+\mu_{24}+\mu_{25}\right)
$$

Ignoring the common factor, we can specify this contrast as

$$
\{\text { race\#agegrp -1 - } 1-1-1-1111111111000000\}
$$

contrast will fill in the trailing zeros for us if we neglect to specify them, so

$$
\{\text { race\#agegrp -1 -1 -1 -1 }-1
$$

is also allowed. The other constraint, $\mu_{1}=\mu_{3 .}$, translates to

$$
\frac{1}{5}\left(\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}\right)=\frac{1}{5}\left(\mu_{31}+\mu_{32}+\mu_{33}+\mu_{34}+\mu_{35}\right)
$$

This can be specified to contrast as

```
\{race\#agegrp - \(1-1-1-1-10000011111\}\)
```

The following call to contrast yields the same test results as above.

```
. contrast {race#agegrp -1 -1 -1 -1 -1 1 1 1 1 1 1}
> {race#agegrp -1 -1 -1 -1 -1 0 0 0 0 0 0 1 1 1 1 1 1}, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | :---: | :---: |
| race\#agegrp |  |  |  |
| (1) (1) | 1 | 6.28 | 0.0150 |
| (2) (2) | 1 | 4.41 | 0.0399 |
| Joint | 2 | 3.62 | 0.0329 |
| Denominator | 60 |  |  |

The row labeled (1) (1) is the test for

$$
\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}=\mu_{21}+\mu_{22}+\mu_{23}+\mu_{24}+\mu_{25}
$$

It was the first specified contrast. The row labeled (2) (2) is the test for

$$
\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}=\mu_{31}+\mu_{32}+\mu_{33}+\mu_{34}+\mu_{35}
$$

It was the second specified contrast. The row labeled Joint tests (1) (1) and (2) (2) simultaneously.
We used the noeffects option above to suppress the table of contrasts. We can omit the $1 / 5$ from the equations for $\mu_{1}=\mu_{2}$. and $\mu_{1}=\mu_{3}$. and still obtain the appropriate tests. However, if we want to calculate the differences in the marginal means, we must include the $1 / 5=0.2$ on each of the contrast coefficients as follows:

```
. contrast {race#agegrp -0.2 -0.2 -0.2 -0.2 -0.2 ///
    0.2
    {race#agegrp -0.2 -0.2 -0.2 -0.2 -0.2 ///
    0}00000001/
    0.2
```

So far, we have reproduced the reference category contrasts by specifying user-defined contrasts on the marginal means and then on the cell means. For this test, it would have been easier to use the r. contrast operator:

```
. contrast r.race, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | ---: |
| race |  |  |  |
| (White vs Black) | 1 | 6.28 | 0.0150 |
| (Other vs Black) | 1 | 4.41 | 0.0399 |
| Joint | 2 | 3.62 | 0.0329 |
| Denominator | 60 |  |  |

In most cases, we can use contrast operators to perform tests. However, if we want to compare, for instance, the second and third age groups with the fourth and fifth age groups with the test

$$
\frac{1}{2}\left(\mu_{\cdot 2}+\mu \cdot 3\right)=\frac{1}{2}\left(\mu_{\cdot 4}+\mu_{\cdot 5}\right)
$$

there is not a contrast operator that corresponds to this particular contrast. A custom contrast is necessary.
. contrast \{agegrp $0-0.5-0.50 .50 .5\}$
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| agegrp | 1 | 62.19 | 0.0000 |
| Denominator | 60 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: |
| agegrp <br> $(1)$ | 19.58413 | 2.483318 | 14.61675 | 24.5515 |

## Empty cells

An empty cell is a combination of the levels of factor variables that is not observed in the estimation sample. In the previous examples, we have seen data with three levels of race, five levels of agegrp, and all level combinations of race and agegrp present. Suppose there are no observations for white individuals in the second age group (ages 20-29).

```
. use https://www.stata-press.com/data/r18/cholesterol2
(Artificial cholesterol data, empty cells)
. label list
race:
    1 Black
    2 White
    3 Other
ages:
    1 10-19
    2 20-29
    3 30-39
    4 40-59
    5 60-79
```

. regress chol race\#\#agegrp
note: 2.race\#2.agegrp identifies no observations in the sample.

| Other\#60-79 | -1.578052 | 8.470719 | -0.19 | 0.853 | -18.54694 | 15.39084 |
| _cons | 175.2309 | 4.235359 | 41.37 | 0.000 | 166.7464 | 183.7153 |

Now, let's use contrast to test the main effects of race:
. contrast race
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| race | (not testable) |  |  |
| Denominator | 56 |  |  |

By "not testable", contrast means that it cannot form a test for the main effects of race based on estimable functions of the model coefficients. agegrp has five levels, so contrast constructs an estimate of the $i$ th margin for race as

$$
\widehat{\mu}_{i}=\frac{1}{5} \sum_{j=1}^{5} \widehat{\mu}_{i j}=\widehat{\mu}_{0}+\widehat{\alpha}_{i}+\frac{1}{5} \sum_{j=1}^{5}\left\{\widehat{\beta}_{j}+(\widehat{\alpha \beta})_{i j}\right\}
$$

but $(\widehat{\alpha \beta})_{22}$ was constrained to zero because of the empty cell, so $\widehat{\mu}_{2}$. is not an estimable function of the model coefficients.

See Estimable functions in Methods and formulas of [R] margins for a technical description of estimable functions. The emptycells (reweight) option causes contrast to estimate $\mu_{2}$. by

$$
\widehat{\mu}_{2 .}=\frac{\widehat{\mu}_{21}+\widehat{\mu}_{23}+\widehat{\mu}_{24}+\widehat{\mu}_{25}}{4}
$$

which is an estimable function of the model coefficients.

```
. contrast race, emptycells(reweight)
Contrasts of marginal linear predictions
Margins: asbalanced
Empty cells: reweight
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| race | 2 | 3.17 | 0.0498 |
| Denominator | 56 |  |  |

We can reconstruct the effect of the emptycells (reweight) option by using custom contrasts.

```
. contrast {race#agegrp -4 -4 -4 -4 -4 5 0 5 5 5}
> {race#agegrp -1 -1 -1 -1 -1 0 0 0 0 0 0 1 1 1 1 1 1}, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| race\#agegrp |  |  |  |
| (1) (1) | 1 | 1.06 | 0.3080 |
| (2) (2) | 1 | 2.37 | 0.1291 |
| Joint | 2 | 3.17 | 0.0498 |
| Denominator | 56 |  |  |

The row labeled (1) (1) is the test for

$$
\frac{1}{5}\left(\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}\right)=\frac{1}{4}\left(\mu_{21}+\mu_{23}+\mu_{24}+\mu_{25}\right)
$$

It was the first specified contrast. The row labeled (2) (2) is the test for

$$
\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}=\mu_{31}+\mu_{32}+\mu_{33}+\mu_{34}+\mu_{35}
$$

It was the second specified contrast. The row labeled Joint is the overall test of the main effects of race.

## Empty cells, ANOVA style

Let's refit the linear model from the previous example with anova to compare with contrast's test for the main effects of race.

|  | $\begin{aligned} \text { Number of obs } & = \\ \text { Root MSE } & = \end{aligned}$ | $\begin{array}{r} 70 \\ 9.47055 \end{array}$ | R-squared = <br> Adj R-squared $=$ |  | $\begin{aligned} & 0.7582 \\ & 0.7021 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 15751.611 | 13 | 1211.6624 | 13.51 | 0.0000 |
| race | 305.49046 | 2 | 152.74523 | 1.70 | 0.1914 |
| agegrp | 14387.856 | 4 | 3596.964 | 40.10 | 0.0000 |
| race\#agegrp | 795.80757 | 7 | 113.6868 | 1.27 | 0.2831 |
| Residual | 5022.7156 | 56 | 89.69135 |  |  |
| Total | 20774.327 | 69 | 301.0772 |  |  |

contrast and anova handled the empty cell differently; the $F$ statistic reported by contrast was 3.17 , but anova reported 1.70 . To see how they differ, consider the following table of the cell means and margins for our situation.

|  |  | agegrp |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 1 | 2 | 3 | 4 | 5 |  |
|  | 1 | $\mu_{11}$ | $\mu_{12}$ | $\mu_{13}$ | $\mu_{14}$ | $\mu_{15}$ | $\mu_{1}$. |
| race | 2 | $\mu_{21}$ |  | $\mu_{23}$ | $\mu_{24}$ | $\mu_{25}$ |  |
|  | 3 | $\mu_{31}$ | $\mu_{32}$ | $\mu_{33}$ | $\mu_{34}$ | $\mu_{35}$ | $\mu_{3}$. |
|  |  | $\mu_{\cdot 1}$ |  | $\mu_{\cdot 3}$ | $\mu_{\cdot 4}$ | $\mu_{\cdot 5}$ |  |

For testing the main effects of race, we know that we will be testing the equality of the marginal means for rows 1 and 3 , that is, $\mu_{1}=\mu_{3}$. This translates into the following constraint:

$$
\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}=\mu_{31}+\mu_{32}+\mu_{33}+\mu_{34}+\mu_{35}
$$

Because row 2 contains an empty cell in column 2, anova dropped column 2 and tested the equality of the marginal mean for row 2 with the average of the marginal means from rows 1 and 3 , using only the remaining cell means. This translates into the following constraint:

$$
\begin{equation*}
2\left(\mu_{21}+\mu_{23}+\mu_{24}+\mu_{25}\right)=\mu_{11}+\mu_{13}+\mu_{14}+\mu_{15}+\mu_{31}+\mu_{33}+\mu_{34}+\mu_{35} \tag{1}
\end{equation*}
$$

Now that we know the constraints that anova used to test for the main effects of race, we can use custom contrasts to reproduce the anova test result.

```
. contrast {race#agegrp -1 -1 -1 -1 -1 0 0 0 0 0 0 1 1 1 1 1 1}
> {race#agegrp 1 0 0 1 1 1 1 -2 0 -2 --2 -2 1 0 1 1 1 1}, noeffects
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| race\#agegrp |  |  |  |
| (1) (1) | 1 | 2.37 | 0.1291 |
| (2) (2) | 1 | 1.03 | 0.3138 |
| Joint | 2 | 1.70 | 0.1914 |
| Denominator | 56 |  |  |

The row labeled (1) (1) is the test for $\mu_{1}=\mu_{3}$.; it was the first specified contrast. The row labeled (2) (2) is the test for the constraint in (1); it was the second specified contrast. The row labeled Joint is an overall test for the main effects of race.

## Nested effects

contrast has the $\mid$ operator for computing simple effects when the levels of one factor are nested within the levels of another. Here is a fictional example where we are interested in the effect of five methods of teaching algebra on students' scores for the math portion of the SAT. Suppose three algebra classes are randomly sampled from classes using each of the five methods so that class is nested in method as demonstrated in the following tabulation.
. use https://www.stata-press.com/data/r18/sat
(Fictional SAT data)
• tabulate class method
Class ID

We will consider method as fixed and class nested in method as random. To use class nested in method as the error term for method, we can specify the following anova model:

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 75 \\ 71.8517 \end{array}$ | R-squared = <br> Adj R-squared = |  | $\begin{aligned} & 0.7599 \\ & 0.7039 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 980312 | 14 | 70022.286 | 13.56 | 0.0000 |
| method | 905872 | 4 | 226468 | 30.42 | 0.0000 |
| class\|method | 74440 | 10 | 7444 |  |  |
| class/method | 74440 | 10 | 7444 | 1.44 | 0.1845 |
| Residual | 309760 | 60 | 5162.6667 |  |  |
| Total | 1290072 | 74 | 17433.405 |  |  |

Like anova, contrast allows the | operator, which specifies that one variable is nested in the levels of another. We can use contrast to test the main effects of method and the simple effects of class within method.
. contrast method class|method
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | ---: |
| method | (not testable) |  |  |
| classlmethod |  |  |  |
| 1 |  | 2.80 | 0.0687 |
| 2 | 2 | 0.91 | 0.4089 |
| 3 | 2 | 1.10 | 0.3390 |
| 4 | 2 | 0.22 | 0.8025 |
| 5 | 2 | 2.18 | 0.1221 |
| Joint | 2 | 1.44 | 0.1845 |
|  | 10 |  |  |
| Denominator |  |  |  |

Although contrast was able to perform the individual tests for the simple effects of class within method, empty cells in the interaction between method and class prevented contrast from testing for a main effect of method. Here we add the emptycells (reweight) option so that contrast can take the empty cells into account when computing the marginal means for method.

```
. contrast method class|method, emptycells(reweight)
Contrasts of marginal linear predictions
Margins: asbalanced
Empty cells: reweight
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| method | 4 | 43.87 | 0.0000 |
| class\|method |  |  |  |
| 1 | 2 | 2.80 | 0.0687 |
| 2 | 2 | 0.91 | 0.4089 |
| 3 | 2 | 1.10 | 0.3390 |
| 4 | 2 | 0.22 | 0.8025 |
| 5 | 2 | 2.18 | 0.1221 |
| Joint | 10 | 1.44 | 0.1845 |
|  |  |  |  |
| Denominator | 60 |  |  |

Now, contrast does report a test for the main effects of method. However, if we compare this with the anova results, we will see that the results are different. They are different because contrast uses the residual error term to compute the $F$ test by default. Using notation similar to anova, we can use the / operator to specify a different error term for the test. Therefore, we can reproduce the test of main effects from our anova command by typing

```
. contrast method / class|method /, emptycells(reweight)
Contrasts of marginal linear predictions
Margins: asbalanced
Empty cells: reweight
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | :---: | ---: |
| method | 4 | 30.42 | 0.0000 |
| class\|method | 10 | (denominator) |  |
| class\|method |  |  |  |
| 1 | 2 | 2.80 | 0.0687 |
| 2 | 2 | 0.91 | 0.4089 |
| 3 | 2 | 1.10 | 0.3390 |
| 4 | 2 | 0.22 | 0.8025 |
| 5 | 2 | 2.18 | 0.1221 |
| Joint | 10 | 1.44 | 0.1845 |
|  |  |  |  |
| Denominator | 60 |  |  |

## Multiple comparisons

We have seen that contrast can report the individual linear combinations that make up the requested effects. Depending upon the specified option, contrast will report confidence intervals, $p$-values, or both in the effects table. By default, the reported confidence intervals and $p$-values are not adjusted for multiple comparisons. Use the mcompare () option to adjust the confidence intervals and $p$-values for multiple comparisons of the individual effects.

Let's compute the grand mean effects of race using the g . operator. We also specify the mcompare(bonferroni) option to compute $p$-values and confidence intervals using Bonferroni's adjustment.

```
- use https://www.stata-press.com/data/r18/cholesterol
(Artificial cholesterol data)
- anova chol race\#\#agegrp
    (output omitted)
. contrast g.race, mcompare(bonferroni)
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | Bonferroni |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | $\mathrm{P}>\mathrm{F}$ | $\mathrm{P}>\mathrm{F}$ |
| race |  |  |  |  |
| (Black vs mean) | 1 | 7.07 | 0.0100 | 0.0301 |
| (White vs mean) | 1 | 2.82 | 0.0982 | 0.2947 |
| (Other vs mean) | 1 | 0.96 | 0.3312 | 0.9936 |
| Joint | 2 | 3.62 | 0.0329 |  |
| Denominator | 60 |  |  |  |

Note: Bonferroni-adjusted p-values are reported for tests on individual contrasts only.

|  | Number of <br> comparisons |
| ---: | ---: |
| race | 3 |

|  |  |  | Bonferroni <br> [95\% conf. interval] |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Contrast | Std. err. |  |  |
| race |  |  |  |  |
| (Black vs mean) | 4.17666 | 1.570588 | .3083743 | 8.044945 |
| (White vs mean) | -2.638058 | 1.570588 | -6.506343 | 1.230227 |
| (Other vs mean) | -1.538602 | 1.570588 | -5.406887 | 2.329684 |

The last table reports a Bonferroni-adjusted confidence interval for each individual contrast. (Use the effects option to add $p$-values to the last table.) The first table includes a Bonferroni-adjusted $p$-value for each test that is not a joint test.

Joint tests are never adjusted for multiple comparisons. For example,

```
. contrast race@agegrp, mcompare(bonferroni)
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | :---: | :---: |
| race@agegrp |  |  |  |
| $10-19$ | 2 | 1.37 | 0.2620 |
| $20-29$ | 2 | 2.44 | 0.0958 |
| $30-39$ | 2 | 3.12 | 0.0512 |
| $40-59$ | 2 | 0.53 | 0.5889 |
| 60-79 | 2 | 2.90 | 0.0628 |
| Joint | 10 | 2.07 | 0.0409 |
| Denominator | 60 |  |  |

Note: Bonferroni-adjusted p-values are reported for tests on individual contrasts only.

|  | Number of <br> comparisons |
| ---: | ---: |
| race@agegrp | 10 |

|  |  |  | Bonferroni <br> [95\% conf. interval] |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Contrast | Std. err. |  |  |
| (White vs base) $10-19$ | 6.841855 | 6.082862 | -10.88697 | 24.57068 |
| (White vs base) 20-29 | -11.80631 | 6.082862 | -29.53513 | 5.922513 |
| (White vs base) 30-39 | -14.40607 | 6.082862 | -32.13489 | 3.322751 |
| (White vs base) 40-59 | -4.101691 | 6.082862 | -21.83051 | 13.62713 |
| (White vs base) 60-79 | -10.60137 | 6.082862 | -28.33019 | 7.127448 |
| (Other vs base) 10-19 | -2.975244 | 6.082862 | -20.70407 | 14.75358 |
| (Other vs base) 20-29 | -11.45679 | 6.082862 | -29.18561 | 6.272031 |
| (Other vs base) 30-39 | -11.41958 | 6.082862 | -29.1484 | 6.309244 |
| (Other vs base) 40-59 | -6.17807 | 6.082862 | -23.90689 | 11.55075 |
| (Other vs base) $60-79$ | 3.453375 | 6.082862 | -14.27545 | 21.1822 |

Here we have five tests of simple effects with two degrees of freedom each. No Bonferroni-adjusted $p$-values are available for these tests, but the confidence intervals for the individual contrasts are adjusted.

## Unbalanced data

By default, contrast treats all factors as balanced when computing marginal means. By balanced, we mean that contrast assumes an equal number of observations in each level of each factor and an equal number of observations in each cell of each interaction. If our data are balanced, there is no issue. If, however, our data are not balanced, we might prefer that contrast use the actual cell frequencies from our data in computing marginal means. We instruct contrast to use observed frequencies by adding the asobserved option.

Even if our data are unbalanced, we might still want contrast to compute balanced marginal means. It depends on what we want to test and what our data represent. If we have data from a designed
experiment that started with an equal number of males and females but the data became unbalanced because the data from a few males were unusable, we might still want our margins computed as though the data were balanced. If, however, we have a representative sample of individuals from Los Angeles with 40\% of European descent, 34\% African-American, 25\% Hispanic, and 1\% Australian, we probably want our margins computed using these representative frequencies. We do not want Australians receiving the same weight as Europeans.

The following examples will use an unbalanced version of our dataset.

```
. use https://www.stata-press.com/data/r18/cholesterol3
(Artificial cholesterol data, unbalanced)
```

. tab race agegrp

| Race | 10-19 | $20-29$ | Age group <br> $30-39$ | $40-59$ | $60-79$ | Total |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Black | 1 | 5 | 5 | 4 | 3 | 18 |
| White | 4 | 5 | 7 | 4 | 4 | 24 |
| Other | 3 | 7 | 6 | 5 | 4 | 25 |
| Total | 8 | 17 | 18 | 13 | 11 | 67 |

The row labeled Total gives observed cell frequencies for age group. These can be obtained by summing frequencies from the cells in the corresponding column. In this respect, we can also refer to them as marginal frequencies. We use the terms marginal frequencies and cell frequencies interchangeably below.

We begin by fitting the two-factor model with an interaction.
. anova chol race\#\#agegrp

## Using observed cell frequencies

Recall that the marginal means are computed from the cell means. Treating the factors as balanced yields the following marginal means for race:

$$
\begin{aligned}
& \eta_{1 .}=\frac{1}{5}\left(\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}\right) \\
& \eta_{2 .}=\frac{1}{5}\left(\mu_{21}+\mu_{22}+\mu_{23}+\mu_{24}+\mu_{25}\right) \\
& \eta_{3 .}=\frac{1}{5}\left(\mu_{31}+\mu_{32}+\mu_{33}+\mu_{34}+\mu_{35}\right)
\end{aligned}
$$

If we have a fixed population and unbalanced cells, then the $\eta_{i}$. do not represent population means. If, however, our data are representative of the population, we can use the frequencies from our estimation sample to estimate the population marginal means, denoted $\mu_{i}$.

Here are the results of testing for a main effect of race, treating all the factors as balanced.

```
. contrast r.race
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | ---: |
| race |  |  |  |
| (White vs Black) | 1 | 3.28 | 0.0757 |
| (Other vs Black) | 1 | 1.50 | 0.2263 |
| Joint | 2 | 1.64 | 0.2029 |
| Denominator | 52 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: |
| race |  |  |  |  |
| (White vs Black) | -5.324254 | 2.93778 | -11.21934 | .5708338 |
| (Other vs Black) | -3.596867 | 2.93778 | -9.491955 | 2.298221 |

The row labeled (White vs Black) is the test for $\eta_{2} .=\eta_{1}$.. The row labeled (Other vs Black) is the test for $\eta_{3}=\eta_{1}$..

If the observed marginal frequencies are representative of the distribution of the levels of agegrp, we can use them to form the marginal means of chol for each of the levels of race from the cell means.

$$
\begin{aligned}
& \mu_{1 .}=\frac{1}{67}\left(8 \mu_{11}+17 \mu_{12}+18 \mu_{13}+13 \mu_{14}+11 \mu_{15}\right) \\
& \mu_{2 .}=\frac{1}{67}\left(8 \mu_{21}+17 \mu_{22}+18 \mu_{23}+13 \mu_{24}+11 \mu_{25}\right) \\
& \mu_{3 .}=\frac{1}{67}\left(8 \mu_{31}+17 \mu_{32}+18 \mu_{33}+13 \mu_{34}+11 \mu_{35}\right)
\end{aligned}
$$

Here are the results of testing for the main effects of race, using the observed marginal frequencies:

```
. contrast r.race, asobserved
Contrasts of marginal linear predictions
Margins: asobserved
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| race |  |  |  |
| (White vs Black) | 1 | 7.25 | 0.0095 |
| (Other vs Black) | 1 | 3.89 | 0.0538 |
| Joint | 2 | 3.74 | 0.0304 |
| Denominator | 52 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | :--- | :--- | :--- | :--- |
| race |  |  |  |  |
| (White vs Black) | -7.232433 | 2.686089 | -12.62246 | -1.842402 |
| (Other vs Black) | -5.231198 | 2.651203 | -10.55123 | .0888295 |

The row labeled (White vs Black) is the test for $\mu_{2} .=\mu_{1}$.. The row labeled (Other vs Black) is the test for $\mu_{3}$. $=\mu_{1}$.. Both tests were insignificant when we tested the cell means resulting from balanced frequencies; however, when we tested the cell means from observed frequencies, the first test is significant beyond the $5 \%$ level (and the second test is nearly so).

Here we reproduce the results of the asobserved option with custom contrasts. Because we are modifying the way that the marginal means are constructed from the cell means, we will specify the contrasts on the predicted cell means. We use macro expansion, =exp, to evaluate the fractions instead of approximating them with decimals. Macro expansion guarantees that the contrast coefficients sum to zero. For more information, see Macro expansion operators and function in [P] macro.

```
. contrast {race#agegrp -'=8/67' - '=17/67' - '=18/67' -'=13/67' - '=11/67'
> '=8/67, '=17/67, '=18/67, '=13/67, '=11/67'}
> {race#agegrp -'{=8/67' -'=17/67' -'{=18/67' -'=13/67' -'=11/67'
> 0
> '=8/67' '=17/67' '=18/67' '=13/67' '=11/67'}
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| race\#agegrp |  |  |  |
| (1) (1) | 1 | 7.25 | 0.0095 |

## Weighted contrast operators

contrast provides observation-weighted versions of five of the contrast operators-gw., hw., jw., pw., and qw.. The first three of these operators perform comparisons of means across cells, and like the marginal means just discussed, these means can be computed in two ways: 1) as though the cell frequencies were equal or 2) using the observed cell frequencies from the estimation sample. The weighted operators provide versions of the standard (as balanced) operators that weight these means by their cell frequencies. The two orthogonal polynomial operators involve similar adjustments for weighting.

Let's examine what this means by using the gw. operator. The gw. operator is a weighted version of the g . operator. The gw. operator computes the grand mean using the cell frequencies for race obtained from the model fit.

Here we test the effects of race, comparing each level with the weighted grand mean but otherwise treating the factors as balanced in the marginal mean calculations.
. contrast gw.race
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | $F$ | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | ---: |
| race |  |  |  |
| (Black vs mean) | 1 | 2.78 | 0.1014 |
| (White vs mean) | 1 | 2.06 | 0.1573 |
| (Other vs mean) | 1 | 0.06 | 0.8068 |
| Joint | 2 | 1.64 | 0.2029 |
| Denominator | 52 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | ---: | ---: | ---: |
| race |  |  |  |  |
| (Black vs mean) | 3.24931 | 1.948468 | -.6605779 | 7.159198 |
| (White vs mean) | -2.074944 | 1.44618 | -4.976915 | .8270276 |
| (Other vs mean) | -.347557 | 1.414182 | -3.18532 | 2.490206 |

The observed marginal frequencies of race are 18,24 , and 25 . Thus, the row labeled (Black vs Mean) tests $\eta_{1} .=\left(18 \eta_{1} .+24 \eta_{2} .+25 \eta_{3 .}\right) / 67$; the row labeled (White vs Mean) tests $\eta_{2}=\left(18 \eta_{1} .+\right.$ $\left.24 \eta_{2} .+25 \eta_{3 .}\right) / 67$; and the row labeled (Other vs Mean) tests $\eta_{3 .}=\left(18 \eta_{1 .}+24 \eta_{2} .+25 \eta_{3 .}\right) / 67$.

Now, we reproduce the above results using custom contrasts. We are weighting the calculation of the grand mean from the marginal means for each of the races, but we are not weighting the calculation of the marginal means themselves. Therefore, we can specify the custom contrast on the marginal means for race instead of on the cell means.

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | :---: | :---: |
| race |  |  |  |
| (1) | 1 | 2.78 | 0.1014 |
| (2) | 1 | 2.06 | 0.1573 |
| (3) | 1 | 0.06 | 0.8068 |
| Joint | 2 | 1.64 | 0.2029 |
| Denominator | 52 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | ---: | ---: | ---: |
| race |  |  |  |  |
| $(1)$ | 3.24931 | 1.948468 | -.6605779 | 7.159198 |
| $(2)$ | -2.074944 | 1.44618 | -4.976915 | .8270276 |
| $(3)$ | -.347557 | 1.414182 | -3.18532 | 2.490206 |

Now, we will test for each race the difference between the marginal mean and the weighted grand mean, treating the factors as observed in the marginal mean calculations.
. contrast gw.race, asobserved wald ci
Contrasts of marginal linear predictions
Margins: asobserved

|  | df | $F$ | $P>F$ |
| :---: | :---: | :---: | :---: |
| race |  |  |  |
| (Black vs mean) | 1 | 6.81 | 0.0118 |
| (White vs mean) | 1 | 3.74 | 0.0587 |
| (Other vs mean) | 1 | 0.26 | 0.6099 |
| Joint | 2 | 3.74 | 0.0304 |
| Denominator | 52 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :--- | ---: | ---: | ---: | ---: |
| race |  |  |  |  |
| (Black vs mean) | 4.542662 | 1.740331 | 1.050432 | 8.034891 |
| (White vs mean) | -2.689771 | 1.39142 | -5.481859 | .1023172 |
| (Other vs mean) | -.6885363 | 1.341261 | -3.379973 | 2.002901 |

The row labeled (Black vs Mean) tests $\mu_{1}=\left(18 \mu_{1}+24 \mu_{2}+25 \mu_{3}.\right) / 67$; the row labeled (White vs Mean) tests $\mu_{2}=\left(18 \mu_{1}+24 \mu_{2}+25 \mu_{3}.\right) / 67$; and the row labeled (Other vs Mean) tests $\mu_{3}=\left(18 \mu_{1} .+24 \mu_{2}+25 \mu_{3}.\right) / 67$.

Here we use a custom contrast to reproduce the above result testing $\mu_{1}=\left(18 \mu_{1} .+24 \mu_{2} .+\right.$ $25 \mu_{3}$.) /67. Because both the calculation of the marginal means and the calculation of the grand mean are adjusted, we specify the custom contrast on the cell means.

| . contrast \{race\#agegrp | ${ }^{\prime}=49 / 67 * 8 / 67$ ' | $'=49 / 67 * 17 / 67$ ' | $'=49 / 67 * 18 / 67$ ' |
| :---: | :---: | :---: | :---: |
| > | ${ }^{\prime}=49 / 67 * 13 / 67$, | ${ }^{\prime}=49 / 67 * 11 / 67$ |  |
| > | - ' $=24 / 67 * 8 / 67$ ' | $-^{\prime}=24 / 67 * 17 / 67$ ' | = $24 / 67 * 18 / 67$, |
| > | $-^{\prime}=24 / 67 * 13 / 67$ ' | $-^{\prime}=24 / 67 * 11 / 67$ |  |
| $>$ | - ' $=25 / 67 * 8 / 67$ ' | $\mathrm{l}^{\prime}=25 / 67 * 17 / 67$ ' | = $25 / 67 * 18 / 67$, |
| > | $-^{\prime}=25 / 67 * 13 / 67$ ' | $-^{\prime}=25 / 67 * 11 / 67$ | , nowald |
| Contrasts of marginal linear predictions |  |  |  |
| Margins: asbalanced |  |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: |
| race\#agegrp <br> (1) (1) | 4.542662 | 1.740331 | 1.050432 | 8.034891 |

The Helmert and reverse Helmert contrasts also involve calculating averages of the marginal means; therefore, weighted versions of these parameters are available as well. The hw. operator is a weighted version of the $h$. operator that computes the mean of the subsequent levels using the cell frequencies obtained from the model fit. The $j w$. operator is a weighted version of the $j$. operator that computes the mean of the previous levels using the cell frequencies obtained from the model fit.

For orthogonal polynomials, we can use the pw. and qw. operators, which are the weighted versions of the p . and q. operators. In this case, the cell frequencies from the model fit are used in the calculation of the orthogonal polynomial contrast coefficients.

## Testing factor effects on slopes

For linear models where the independent variables are all factor variables, the linear prediction at fixed levels of the factor variables turns out to be a cell mean. With these models, contrast computes and tests the effects of the factor variables on the expected mean of the dependent variable. When factor variables are interacted with continuous variables, contrast distinguishes factor effects on the intercept from factor effects on the slope.

Here we have 1980 census data including information on the birthrate (brate), the median age (medage), and the region of the country (region) for each of the 50 states. We can fit an ANCOVA model for brate using main effects of the factor variable region and the continuous variable medage.

```
. use https://www.stata-press.com/data/r18/census3
(1980 Census data by state)
. label list cenreg
cenreg:
    1 NE
    2 ~ N C e n t r a l ~
    3 South
    4 West

\end{tabular}
```

For those more comfortable with linear regression, this is equivalent to the regression model

```
. regress brate i.region c.medage
```

You may use either.
We can use contrast to compute reference category effects for region. These contrasts compare the adjusted means of NCentral, South, and West regions with the adjusted mean of the NE region.

```
. contrast r.region
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | ---: | ---: |
| region |  |  |  |
| (NCentral vs NE) | 1 | 2.24 | 0.1417 |
| (South vs NE) | 1 | 0.78 | 0.3805 |
| (West vs NE) | 1 | 10.33 | 0.0024 |
| Joint | 3 | 4.50 | 0.0076 |
| Denominator | 45 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: |
| region |  |  |  |  |
| (NCentral vs NE) | 9.061063 | 6.057484 | -3.139337 | 21.26146 |
| (South vs NE) | 5.06991 | 5.72396 | -6.458738 | 16.59856 |
| (West vs NE) | 21.71328 | 6.755616 | 8.106774 | 35.31979 |

Let's add the interaction between region and medage to the model.
. anova brate region\#\#c.medage

|  | $\begin{array}{ll} \text { Number of obs } & = \\ \text { Root MSE } & = \end{array}$ | $\begin{array}{r} 50 \\ 10.0244 \end{array}$ | R-squared = <br> Adj R-squared $=$ |  | $\begin{aligned} & 0.9000 \\ & 0.8833 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Source | Partial SS | df | MS | F | Prob>F |
| Model | 37976.315 | 7 | 5425.1878 | 53.99 | 0.0000 |
| region | 3405.0704 | 3 | 1135.0235 | 11.30 | 0.0000 |
| medage | 5279.7145 | 1 | 5279.7145 | 52.54 | 0.0000 |
| region\#medage | 3103.456 | 3 | 1034.4853 | 10.29 | 0.0000 |
| Residual | 4220.5051 | 42 | 100.48822 |  |  |
| Total | 42196.82 | 49 | 861.15959 |  |  |

The parameterization for the expected value of brate as a function of region and medage is given by

$$
E(\text { brate } \mid \text { region }=i, \text { medage })=\alpha_{0}+\alpha_{i}+\beta_{0} \text { medage }+\beta_{i} \text { medage }
$$

where $\alpha_{0}$ is the intercept and $\beta_{0}$ is the slope of medage. We are modeling the effects of region in two different ways. The $\alpha_{i}$ parameters measure the effect of region on the intercept, and the $\beta_{i}$ parameters measure the effect of region on the slope of medage.
contrast computes and tests effects on slopes separately from effects on intercepts. First, we will compute the reference category effects of region on the intercept:

```
. contrast r.region
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | ---: | ---: | ---: |
| region |  |  |  |
| (NCentral vs NE) | 1 | 0.09 | 0.7691 |
| (South vs NE) | 1 | 0.01 | 0.9389 |
| (West vs NE) | 1 | 8.50 | 0.0057 |
| Joint | 3 | 11.30 | 0.0000 |
| Denominator | 42 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: |
| region |  |  |  |  |
| (NCentral vs NE) | -49.38396 | 167.1281 | -386.6622 | 287.8942 |
| (South vs NE) | -9.058983 | 117.424 | -246.0302 | 227.9123 |
| (West vs NE) | 343.0024 | 117.6547 | 105.5656 | 580.4393 |

Now, we will compute the reference category effects of region on the slope of medage:

```
. contrast r.region#c.medage
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | ---: | ---: |
| region\#c.medage |  |  |  |
| (NCentral vs NE) | 1 | 0.16 | 0.6917 |
| (South vs NE) | 1 | 0.03 | 0.8558 |
| (West vs NE) | 1 | 8.18 | 0.0066 |
| Joint | 3 | 10.29 | 0.0000 |
| Denominator | 42 |  |  |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | :--- | ---: | ---: |
| region\#c.medage |  |  |  |  |
| (NCentral vs NE) | 2.208539 | 5.530981 | -8.953432 | 13.37051 |
| (South vs NE) | .6928008 | 3.788735 | -6.953175 | 8.338777 |
| (West vs NE) | -10.94649 | 3.827357 | -18.67041 | -3.22257 |

At the 5\% level, the slope of medage for the West region differs from that of the NE region, but at that level of significance, we cannot say that the slope for the NCentral or the South region differs from that of the NE region.

This model is simple enough that the reference category contrasts reproduce the coefficients for region and for the interactions in an equivalent model fit by regress.

This will not be the case for models that are more complicated.

## Chow tests

Now, let's suppose we are fitting a model for birthrates on median age and marriage rate. We are also interested in whether the regression coefficients differ for states in the east versus states in the west. We use census divisions to create a new variable, west, that indicates which states are in the western half of the United States.

```
. generate west = inlist(division, 4, 7, 8, 9)
```

We fit a model that includes a separate intercept for west as well as an interaction between west and each of the other variables in our model.
. regress brate i.west\#\#c.medage i.west\#\#c.mrgrate

| Source | SS | df | MS |
| ---: | ---: | ---: | :---: |
| Model | 38516.2172 | 5 | 7703.24344 |
| Residual | 3680.60281 | 44 | 83.6500639 |
| Total | 42196.82 | 49 | 861.159592 |

| Number of obs | $=$ | 50 |
| :--- | :--- | ---: |
| F(5, 44) | $=$ | 92.09 |
| Prob > F | $=$ | 0.0000 |
| R-squared | $=$ | 0.9128 |
| Adj R-squared | $=$ | 0.9029 |
| Root MSE | $=$ | 9.146 |

| brate | Coefficient | Std. err. | t | $P>\|t\|$ | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1. west | 327.8733 | 58.71793 | 5.58 | 0.000 | 209.5351 | 446.2115 |
| medage | -7.532304 | 1.387624 | -5.43 | 0.000 | -10.32888 | -4.735731 |
| west\# <br> c.medage |  |  |  |  |  |  |
| 1 | -10.11443 | 1.849103 | -5.47 | 0.000 | -13.84105 | -6.387808 |
| mrgrate | 828.6813 | 643.3443 | 1.29 | 0.204 | -467.8939 | 2125.257 |
| $\begin{gathered} \text { west\# } \\ \text { c.mrgrate } \end{gathered}$ |  |  |  |  |  |  |
| 1 | -800.8036 | 645.488 | -1.24 | 0.221 | -2101.699 | 500.092 |
| _cons | 366.5325 | 47.08904 | 7.78 | 0.000 | 271.6308 | 461.4343 |

We can test the effects of west on the intercept and on the slopes of medage and mrgrate. We will specify all of these effects in a single contrast command and include the overall option to obtain a joint test of effects, that is, a test that the coefficients for eastern states and for western states are equal.

```
. contrast west west#c.medage west#c.mrgrate, overall
```

Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | ---: |
| west | 1 | 31.18 | 0.0000 |
| west\#c.medage | 1 | 29.92 | 0.0000 |
| west\#c.mrgrate | 1 | 1.54 | 0.2213 |
| Overall | 3 | 22.82 | 0.0000 |
| Denominator | 44 |  |  |

This overall test is referred to as a Chow test in econometrics (Chow 1960).

## Beyond linear models

contrast may be used after almost any estimation command, with the added benefit that contrast provides direct support for testing main and interaction effects that is not available in most estimation commands. To illustrate, we will use contrast with results from a logistic regression. Stata's logit command fits logistic regression models, reporting the fitted regression coefficients. The logistic command fits the same models but reports odds ratios. Although contrast can report odds ratios for the computed effects, the tests are all computed from linear combinations of the model coefficients regardless of which estimation command we used.

Suppose we have data on patient satisfaction for three hospitals in a city. Let's begin by fitting a model for satisfied, whether the patient was satisfied with his or her treatment, using the main effects of hospital:

| (Artificial hospital satisfac <br> . logit satisfied i.hospital |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration 0: Log likelihood $=-393.72216$ |  |  |  |  |  |  |
| Iteration 1: Log likelihood $=-387.55736$ |  |  |  |  |  |  |
| Iteration 2: Log likelihood $=-387.4768$ |  |  |  |  |  |  |
| Iteration 3: Log likelihood $=-387.47679$ |  |  |  |  |  |  |
| Logistic regression |  |  |  |  | Number of obs | $=802$ |
|  |  |  |  |  | LR chi2(2) | $=12.49$ |
|  |  |  |  |  | Prob > chi2 | $=0.0019$ |
| Log likelihood $=-387.47679$ |  |  |  |  | Pseudo R2 | $=0.0159$ |
| satisfied | Coefficient | Std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. | interval] |
| hospital |  |  |  |  |  |  |
| 2 | . 5348129 | . 2136021 | 2.50 | 0.012 | . 1161604 | . 9534654 |
| 3 | .7354519 | . 2221929 | 3.31 | 0.001 | . 2999618 | 1.170942 |
| _cons | 1.034708 | . 1391469 | 7.44 | 0.000 | . 7619855 | 1.307431 |

Because there are no other independent variables in this model, the reference category effects of hospital computed by contrast will match the fitted model coefficients, assuming a common reference level.
. contrast r.hospital
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | chi2 | P>chi2 |
| :---: | :---: | ---: | ---: |
| hospital |  |  |  |
| $(2$ vs 1) | 1 | 6.27 | 0.0123 |
| $(3$ vs 1) | 1 | 10.96 | 0.0009 |
| Joint | 2 | 12.55 | 0.0019 |

|  | Contrast | Std. err. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: |
| hospital |  |  |  |  |
| $(2$ vs 1) | .5348129 | .2136021 | .1161604 | .9534654 |
| $(3$ vs 1) | .7354519 | .2221929 | .2999618 | 1.170942 |

We see that the reference category effects are equal to the fitted coefficients. They also have the same interpretation, the difference in $\log$ odds from the reference category. The top table also provides a joint test of these effects, a test of the main effects of hospital.

We also have information on the condition for which each patient is being treated in the variable illness. Here we fit a logistic regression using a two-way crossed model of hospital and illness.

```
. label list illness
illness:
    1 \text { Heart attack}
    2 Stroke
    3 Pneumonia
    4 Lung disease
    5 Kidney failure
. logistic satisfied hospital##illness

| _cons | 2.571429 | . 8099239 | 3.00 | 0.003 | 1.386983 | 4.767358 |

Note: _cons estimates baseline odds.
Using contrast, we can obtain an ANOVA-style table of tests for the main effects and interaction effects of hospital and illness.

```
. contrast hospital##illness
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | chi2 | P>chi2 |
| ---: | :---: | :---: | :---: |
| hospital | 2 | 14.92 | 0.0006 |
| illness | 4 | 4.09 | 0.3937 |
| hospital\#illness | 8 | 20.45 | 0.0088 |

Our interaction effect is significant, so we decide to evaluate the simple reference category effects of hospital within illness. We are particularly interested in patient satisfaction when being treated for a heart attack or stroke, so we will use the i. operator to limit our output to simple effects within the first two illnesses.

```
. contrast r.hospital@i(1 2).illness, nowald
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | Contrast | Std. err. | [95\% conf | interval] |
| :---: | :---: | :---: | :---: | :---: |
| hospital@illness |  |  |  |  |
| (2 vs 1) Heart attack | . 2041611 | . 4477942 | -. 6734995 | 1.081822 |
| (2 vs 1) Stroke | 1.093722 | . 5721288 | -. 0276296 | 2.215074 |
| (3 vs 1) Heart attack | . 5371429 | . 4710983 | -. 3861928 | 1.460479 |
| (3 vs 1) Stroke | -. 0759859 | . 4662325 | -. 9897847 | . 8378129 |

The row labeled (2 vs 1) heart attack estimates simple effects on the log odds when comparing hospital 2 with hospital 1 for patients having heart attacks. These effects are differences in the cell means of the linear predictions.

We can add the or option to report an odds ratio for each of these simple effects:
. contrast r.hospital@i(1 2).illness, nowald or
Contrasts of marginal linear predictions
Margins: asbalanced

|  | Odds ratio | Std. err. | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: |
| hospital@illness |  |  |  |  |
| (2 vs 1) Heart attack | 1.226496 | . 5492177 | . 509921 | 2.950049 |
| (2 vs 1) Stroke | 2.985366 | 1.708014 | . 9727486 | 9.162089 |
| (3 vs 1) Heart attack | 1.711111 | . 8061016 | . 6796395 | 4.308021 |
| (3 vs 1) Stroke | . 9268293 | . 4321179 | . 3716567 | 2.311306 |

These odds ratios are just the exponentiated version of the contrasts in the previous table.
For contrasts of the margins of nonlinear predictions, such as predicted probabilities, see $[R]$ margins, contrast.

## Multiple equations

contrast works with models containing multiple equations. Commands such as intreg and gnbreg allow their ancillary parameters to be modeled as functions of independent variables, and contrast can compute and test effects within these equations. In addition, contrast allows a special pseudofactor for equation-called _eqns-when working with results from manova, mvreg, mlogit, and mprobit.

In example 4 of [MV] manova, we fit a two-way MANOVA model using data from Woodard (1931). Here we will fit this model using mvreg. The data represent patients with jaw fractures. y1 is the patient's age, y2 is blood lymphocytes, and y3 is blood polymorphonuclears. Two factor variables, gender and fracture, are used as independent variables.
. use https://www.stata-press.com/data/r18/jaw
(Table 4.6. Two-way unbalanced data for fractures of the jaw, Rencher (1998))
. mvreg y1 y2 y3 = gender\#\#fracture, vsquish nofvlabel

| Equation | Obs | Parms | RMSE | "R-sq" | F | P>F |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| y1 | 27 | 6 | 10.21777 | 0.4086 | 2.902124 | 0.0382 |
| y2 | 27 | 6 | 5.268768 | 0.4743 | 3.78967 | 0.0133 |
| y3 | 27 | 6 | 4.993647 | 0.4518 | 3.460938 | 0.0195 |

contrast computes Wald tests using the coefficients from the first equation by default.
. contrast gender\#\#fracture
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | ---: |
| y1 |  |  |  |
| fracture | 1 | 2.16 | 0.1569 |
| gender\#fracture | 2 | 2.74 | 0.0880 |
| Denominator | 2 | 1.69 | 0.2085 |

Here we use the equation() option to compute the Wald tests in the y2 equation:
. contrast gender\#\#fracture, equation(y2)
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | ---: |
| y2 |  |  |  |
| fracture | 1 | 5.41 | 0.0301 |
| gender\#fracture | 2 | 7.97 | 0.0027 |
| Denominator | 2 | 5.97 | 0.0088 |

Here we use the equation index to compute the Wald tests in the third equation:

```
. contrast gender##fracture, equation(#3)
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | :---: |
| y3 |  |  |  |
| fracture | 1 | 2.23 | 0.1502 |
|  | 2 | 6.36 | 0.0069 |
| gender\#fracture | 2 | 6.66 | 0.0058 |
| $r$ Denominator | 21 |  |  |

Here we use the atequations option to compute Wald tests for each equation in the model. We also use the vsquish option to suppress the extra blank lines between terms.
. contrast gender\#\#fracture, atequations vsquish
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | :---: | :---: |
| y1 |  |  |  |
| gender | 1 | 2.16 | 0.1569 |
| fracture | 2 | 2.74 | 0.0880 |
| gender\#fracture | 2 | 1.69 | 0.2085 |
| y2 |  |  |  |
| gender | 1 | 5.41 | 0.0301 |
| fracture | 2 | 7.97 | 0.0027 |
| gender\#fracture | 2 | 5.97 | 0.0088 |
| y3 |  |  |  |
| gender | 1 | 2.23 | 0.1502 |
| fracture | 2 | 6.36 | 0.0069 |
| gender\#fracture | 2 | 6.66 | 0.0058 |
| Denominator | 21 |  |  |

Because we are investigating the results from mvreg, we can use the special _eqns factor to test for a marginal effect on the means among the dependent variables:
. contrast _eqns
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | $F$ | $P>F$ |
| ---: | ---: | ---: | ---: |
| _eqns | 2 | 49.19 | 0.0000 |
| Denominator | 21 |  |  |

Here we test whether the main effects of gender differ among the dependent variables:

| . contrast gender\#_eqns |
| :--- |
| Contrasts of marginal linear predictions |
| Margins: asbalanced |

Although it is not terribly interesting in this case, we can even calculate contrasts across equations:

```
. contrast gender#r._eqns
Contrasts of marginal linear predictions
Margins: asbalanced
```

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| ---: | :---: | :---: | ---: |
| gender\#_eqns |  |  |  |
| (joint)(2 vs 1) | 1 | 5.82 | 0.0251 |
| (joint) (3 vs 1) | 1 | 0.40 | 0.5352 |
| Joint | 2 | 3.61 | 0.0448 |
| Denominator | 21 |  |  |

## Methods and formulas

Methods and formulas are presented under the following headings:

Marginal linear predictions<br>Contrast operators<br>Reference level contrasts<br>Adjacent contrasts<br>Grand mean contrasts<br>Helmert contrasts<br>Reverse Helmert contrasts<br>Orthogonal polynomial contrasts<br>Contrasts within interactions<br>Multiple comparisons

## Marginal linear predictions

contrast treats intercept effects separately from slope effects. To illustrate, consider the following parameterization for a quadratic regression of $y$ on $x$ that also models the effects of two factor variables $A$ and $B$, where the levels of $A$ are indexed by $i=1, \ldots, k_{a}$ and the levels of $B$ are indexed by $j=1, \ldots, k_{b}$.

$$
\begin{aligned}
E(y \mid A=i, B=j, x) & =\eta_{0 i j}+\eta_{1 i j} x+\eta_{2 i j} x^{2} \\
\eta_{0 i j} & =\eta_{0}+\alpha_{0 i}+\beta_{0 j}+(\alpha \beta)_{0 i j} \\
\eta_{1 i j} & =\eta_{1}+\alpha_{1 i}+\beta_{1 j}+(\alpha \beta)_{1 i j} \\
\eta_{2 i j} & =\eta_{2}+\alpha_{2 i}+\beta_{2 j}+(\alpha \beta)_{2 i j}
\end{aligned}
$$

We have partitioned the coefficients into three groups of parameters: $\eta_{0 i j}$ is a cell prediction for the intercept, $\eta_{1 i j}$ is a cell prediction for the slope on $x$, and $\eta_{2 i j}$ is a cell prediction for the slope on $x^{2}$. For the intercept parameters, $\eta_{0}$ is the intercept, $\alpha_{0 i}$ represents a main effect for factor $A$ at its $i$ th level, $\beta_{0 j}$ represents a main effect for factor $B$ at its $j$ th level, and $(\alpha \beta)_{0 i j}$ represents an effect for the interaction of $A$ and $B$ at the $i j$ th level. The individual coefficients in $\eta_{1 i j}$ and $\eta_{2 i j}$ have similar interpretations, but the effects are on the slopes of $x$ and $x^{2}$, respectively.

The marginal intercepts for $A$ are given by

$$
\eta_{0 i .}=\sum_{j=1}^{k_{b}} f_{i j} \eta_{0 i j}
$$

where $f_{i j}$ is a marginal relative frequency of the $j$ th level of $B$ and is controlled by the asobserved and emptycells (reweight) options according to

$$
f_{i j}= \begin{cases}1 / k_{b}, & \text { default } \\ w_{. j} / w_{. .}, & \text {asobserved } \\ 1 /\left(k_{b}-e_{i .}\right), & \text { emptycells(reweight) } \\ w_{i j} / w_{i .}, & \text { emptycells(reweight) and asobserved }\end{cases}
$$

Above, $w_{i j}$ is the number of individuals with $A$ at its $i$ th level and $B$ at its $j$ th,

$$
\begin{gathered}
w_{i .}=\sum_{j=1}^{k_{b}} w_{i j} \\
w_{. j}=\sum_{i=1}^{k_{a}} w_{i j} \\
w_{. .}=\sum_{i=1}^{k_{a}} \sum_{j=1}^{k_{b}} w_{i j}
\end{gathered}
$$

and $e_{i}$. is the number of empty cells where $A$ is at its $i$ th level. The marginal intercepts for $B$ and marginal slopes on $x$ and $x^{2}$ are similarly defined.

Estimates for the cell intercepts and slopes are computed using the corresponding linear combination of the coefficients from the fitted model. For example, the estimated cell intercepts are computed using

$$
\widehat{\eta}_{0 i j}=\widehat{\eta}_{0}+\widehat{\alpha}_{0 i}+\widehat{\beta}_{0 j}+(\widehat{\alpha \beta})_{0 i j}
$$

and the estimated marginal intercepts for $A$ are computed as

$$
\widehat{\eta}_{0 i .}=\sum_{j=1}^{k_{b}} f_{i j} \widehat{\eta}_{0 i j}
$$

## Contrast operators

contrast performs Wald tests using linear combinations of marginal linear predictions. For example, the following linear combination can be used to test for a specific effect of factor $A$ on the marginal intercepts.

$$
\sum_{i=1}^{k_{a}} c_{i} \eta_{0 i}
$$

If the $c_{i}$ elements sum to zero, the linear combination is called a contrast. If the factor $A$ is represented by a variable named A , then we specify this contrast using the following syntax:

$$
\left\{\mathrm{A} c_{1} c_{2} \ldots c_{k_{a}}\right\}
$$

Similarly, the following linear combination can be used to test for a specific interaction effect of factors $A$ and $B$ on the marginal slope of $x$.

$$
\sum_{i=1}^{k_{a}} \sum_{j=1}^{k_{b}} c_{i j} \eta_{1 i j}
$$

If the factor $B$ is represented by a variable named B , then we specify this contrast using the following syntax:

$$
\left\{\mathrm{A} \# \mathrm{~B} c_{11} c_{12} \ldots c_{1 k_{b}} c_{21} \ldots c_{k_{a} k_{b}}\right\}
$$

contrast has variable operators for several commonly used contrasts. Each contrast operator specifies a matrix of linear combinations that yield the requested set of contrasts to be applied to the marginal linear predictions associated with the attached factor variable.

## Reference level contrasts

The r. operator compares each level with a reference level. Let $\mathbf{R}$ be the corresponding contrast matrix for factor $A$, and then $\mathbf{R}$ is a $\left(k_{a}-1\right) \times k_{a}$ matrix with elements

$$
\mathbf{R}_{i j}=\left\{\begin{aligned}
-1, & \text { if } j \text { is the reference level } \\
1, & \text { if } i=j \text { and } j \text { is less than the reference level } \\
1, & \text { if } i+1=j \text { and } j \text { is greater than the reference level } \\
0, & \text { otherwise }
\end{aligned}\right.
$$

If $k_{a}=5$ and the reference level is the third level of $A$ (specified as $\left.\mathrm{rb}(\# 3) . \mathrm{A}\right)$, then

$$
\mathbf{R}=\left(\begin{array}{ccccc}
1 & 0 & -1 & 0 & 0 \\
0 & 1 & -1 & 0 & 0 \\
0 & 0 & -1 & 1 & 0 \\
0 & 0 & -1 & 0 & 1
\end{array}\right)
$$

## Adjacent contrasts

The a. operator compares each level with the next level. Let $\mathbf{A}$ be the corresponding contrast matrix for factor $A$, and then $\mathbf{A}$ is a $\left(k_{a}-1\right) \times k_{a}$ matrix with elements

$$
\mathbf{A}_{i j}=\left\{\begin{aligned}
1, & \text { if } i=j \\
-1, & \text { if } i+1=j \\
0, & \text { otherwise }
\end{aligned}\right.
$$

If $k_{a}=5$, then

$$
\mathbf{A}=\left(\begin{array}{rrrrr}
1 & -1 & 0 & 0 & 0 \\
0 & 1 & -1 & 0 & 0 \\
0 & 0 & 1 & -1 & 0 \\
0 & 0 & 0 & 1 & -1
\end{array}\right)
$$

The ar. operator compares each level with the previous level. If $\mathbf{A}$ is the contrast matrix for the a. operator, then $-\mathbf{A}$ is the corresponding contrast matrix for the ar. operator.

## Grand mean contrasts

The g . operator compares each level with the mean of all the levels. Let $\mathbf{G}$ be the corresponding contrast matrix for factor $A$, and then $\mathbf{G}$ is a $k_{a} \times k_{a}$ matrix with elements

$$
\mathbf{G}_{i j}=\left\{\begin{aligned}
1-1 / k_{a}, & \text { if } i=j \\
-1 / k_{a}, & \text { if } i \neq j
\end{aligned}\right.
$$

If $k_{a}=5$, then

$$
\mathbf{G}=\left(\begin{array}{rrrrr}
4 / 5 & -1 / 5 & -1 / 5 & -1 / 5 & -1 / 5 \\
-1 / 5 & 4 / 5 & -1 / 5 & -1 / 5 & -1 / 5 \\
-1 / 5 & -1 / 5 & 4 / 5 & -1 / 5 & -1 / 5 \\
-1 / 5 & -1 / 5 & -1 / 5 & 4 / 5 & -1 / 5 \\
-1 / 5 & -1 / 5 & -1 / 5 & -1 / 5 & 4 / 5
\end{array}\right)
$$

The gw. operator compares each level with the weighted mean of all the levels. The weights are taken from the observed weighted cell frequencies in the estimation sample of the fitted model. Let $\mathbf{G}_{w}$ be the corresponding contrast matrix for factor $A$, and then $\mathbf{G}_{w}$ is a $k_{a} \times k_{a}$ matrix with elements

$$
\mathbf{G}_{i j}=\left\{\begin{aligned}
1-w_{i} / w ., & \text { if } i=j \\
-w_{j} / w ., & \text { if } i \neq j
\end{aligned}\right.
$$

where $w_{i}$ is a marginal weight representing the number of individuals with $A$ at its $i$ th level and $w .=\sum_{i} w_{i}$.

## Helmert contrasts

The $h$. operator compares each level with the mean of the subsequent levels. Let $\mathbf{H}$ be the corresponding contrast matrix for factor $A$, and then $\mathbf{H}$ is a $\left(k_{a}-1\right) \times k_{a}$ matrix with elements

$$
\mathbf{H}_{i j}= \begin{cases}1, & \text { if } i=j \\ -1 /\left(k_{a}-i\right), & \text { if } i<j \\ 0, & \text { otherwise }\end{cases}
$$

If $k_{a}=5$, then

$$
\mathbf{H}=\left(\begin{array}{ccccl}
1 & -1 / 4 & -1 / 4 & -1 / 4 & -1 / 4 \\
0 & 1 & -1 / 3 & -1 / 3 & -1 / 3 \\
0 & 0 & 1 & -1 / 2 & -1 / 2 \\
0 & 0 & 0 & 1 & -1
\end{array}\right)
$$

The hw. operator compares each level with the weighted mean of the subsequent levels. Let $\mathbf{H}_{w}$ be the corresponding contrast matrix for factor $A$, and then $\mathbf{H}_{w}$ is a $\left(k_{a}-1\right) \times k_{a}$ matrix with elements

$$
\mathbf{H}_{w i j}= \begin{cases}1, & \text { if } i=j \\ -w_{j} / \sum_{l=j}^{k_{a}} w_{l}, & \text { if } i<j \\ 0, & \text { otherwise }\end{cases}
$$

## Reverse Helmert contrasts

The $\mathbf{j}$. operator compares each level with the mean of the previous levels. Let $\mathbf{J}$ be the corresponding contrast matrix for factor $A$, and then $\mathbf{J}$ is a $\left(k_{a}-1\right) \times k_{a}$ matrix with elements

$$
\mathbf{J}_{i j}=\left\{\begin{array}{cl}
1, & \text { if } i+1=j \\
-1 / i, & \text { if } j \leq i \\
0, & \text { otherwise }
\end{array}\right.
$$

If $k_{a}=5$, then

$$
\mathbf{H}=\left(\begin{array}{ccccc}
-1 & 1 & 0 & 0 & 0 \\
-1 / 2 & -1 / 2 & 1 & 0 & 0 \\
-1 / 3 & -1 / 3 & -1 / 3 & 1 & 0 \\
-1 / 4 & -1 / 4 & -1 / 4 & -1 / 4 & 1
\end{array}\right)
$$

The $j w$. operator compares each level with the weighted mean of the previous levels. Let $\mathbf{J}_{w}$ be the corresponding contrast matrix for factor $A$, and then $\mathbf{J}_{w}$ is a $\left(k_{a}-1\right) \times k_{a}$ matrix with elements

$$
\mathbf{J}_{w i j}= \begin{cases}1, & \text { if } i+1=j \\ -w_{j} / \sum_{l=1}^{i} w_{l}, & \text { if } i \leq j \\ 0, & \text { otherwise }\end{cases}
$$

## Orthogonal polynomial contrasts

The p. operator applies orthogonal polynomial contrasts using the level values of the attached factor variable. The q. operator applies orthogonal polynomial contrasts using the level indices of the attached factor variable. These two operators are equivalent when the level values of the attached factor are equally spaced. The pw. and qw. operators are weighted versions of p. and q., where the weights are taken from the observed weighted cell frequencies in the estimation sample of the fitted model. contrast uses the Christoffel-Darboux recurrence formula for computing orthogonal polynomial contrasts (Abramowitz and Stegun 1964). The elements of the contrasts are normalized such that

$$
\mathbf{Q}^{\prime} \mathbf{W Q}=\frac{1}{w .} \mathbf{I}
$$

where $\mathbf{W}$ is a diagonal matrix of the marginal cell weights $w_{1}, w_{2}, \ldots, w_{k}$ of the attached factor variable (all 1 for p . and q .), and $w$. is the sum of the weights (the number of levels $k$ for p . and q.).

## Contrasts within interactions

Contrast operators are allowed to be specified on factor variables participating in interactions. In such cases, contrast applies the proper matrix product of the contrast matrices to the cell margins of the interacted factor variables.

For example, consider the contrasts implied by specifying r.A\#h.B. Let $M$ be the matrix of estimated cell margins for the levels of $A$ and $B$, where the rows of $\mathbf{M}$ are indexed by the levels of $A$ and the columns are indexed by the levels of $B$. contrast puts the estimated cell margins in the following vector form:

$$
\mathbf{v}=\operatorname{vec}\left(\mathbf{M}^{\prime}\right)=\left(\begin{array}{c}
\mathbf{M}_{11} \\
\mathbf{M}_{12} \\
\vdots \\
\mathbf{M}_{1 k_{b}} \\
\mathbf{M}_{21} \\
\mathbf{M}_{22} \\
\vdots \\
\mathbf{M}_{2 k_{b}} \\
\vdots \\
\mathbf{M}_{k_{a} k_{b}}
\end{array}\right)
$$

The individual contrasts are then given by the elements of

$$
(\mathbf{R} \otimes \mathbf{H}) \mathbf{v}
$$

where $\otimes$ denotes the Kronecker direct product.

## Multiple comparisons

See $[R]$ pwcompare for details on the methods and formulas used to adjust $p$-values and confidence intervals for multiple comparisons. The formulas for Bonferroni's method and Šidák's method are presented with $m=k(k-1) / 2$, the number of pairwise comparisons for a factor term with $k$ levels. For contrasts, $m$ is instead the number of contrasts being performed on the factor term; often, $m=k-1$ for a term with $k$ levels.

contrast postestimation - Postestimation tools for contrast
Postestimation commands Remarks and examples Also see

## Postestimation commands

The following postestimation commands are available after contrast, post:
Command Description
estat vce variance-covariance matrix of the estimators (VCE)
estat (svy) postestimation statistics for survey data
estimates cataloging estimation results
etable table of estimation results
lincom point estimates, standard errors, testing, and inference for linear combinations of coefficients
nlcom point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
test Wald tests of simple and composite linear hypotheses
testnl Wald tests of nonlinear hypotheses

## Remarks and examples

In Orthogonal polynomial contrasts in $[\mathrm{R}]$ contrast, we used the p . operator to test the orthogonal polynomial effects of age group.

```
. contrast p.agegrp, noeffects
```

We then used a second contrast command,
. contrast p(2 3 4).agegrp, noeffects
selecting levels to test whether the quadratic, cubic, and quartic contrasts were jointly significant.
We can perform the same joint test by using the test command after specifying the post option with our first contrast command.

```
. use https://www.stata-press.com/data/r18/cholesterol
(Artificial cholesterol data)
```

- anova chol agegrp
(output omitted)
. contrast p.agegrp, noeffects post
Contrasts of marginal linear predictions
Margins: asbalanced

|  | df | F | $\mathrm{P}>\mathrm{F}$ |
| :---: | :---: | ---: | ---: |
| agegrp |  |  |  |
| (linear) | 1 | 139.11 | 0.0000 |
| (quadratic) | 1 | 0.15 | 0.6962 |
| (cubic) | 1 | 0.37 | 0.5448 |
| (quartic) | 1 | 0.43 | 0.5153 |
| Joint | 4 | 35.02 | 0.0000 |
| Denominator | 70 |  |  |

. test p2.agegrp p3.agegrp p4.agegrp
( 1) p2.agegrp $=0$
( 2) p3.agegrp $=0$
( 3) p4.agegrp $=0$
F ( 3, 70) $=0.32$
Prob > F = 0.8129

## Title

copyright - Display copyright information

## Description

copyright presents copyright notifications concerning tools, libraries, etc., used in the construction of Stata.

## Syntax

```
copyright
```

## Remarks and examples

The correct form for a copyright notice is
Copyright dates by author/owner
The word "Copyright" is spelled out. You can use the © symbol, but "(C)" has never been given legal recognition. The phrase "All Rights Reserved" was historically required but is no longer needed.

Currently, most works are copyrighted from the moment they are written, and no copyright notice is required. Copyright concerns the protection of the expression and structure of facts and ideas, not the facts and ideas themselves. Copyright concerns the ownership of the expression and not the name given to the expression, which is covered under trademark law.

Copyright law as it exists today began in England in 1710 with the Statute of Anne, An Act for the Encouragement of Learning, by Vesting the Copies of Printed Books in the Authors or Purchases of Such Copies, during the Times therein mentioned. In 1672, Massachusetts introduced the first copyright law in what was to become the United States. After the Revolutionary War, copyright was introduced into the US Constitution in 1787 and went into effect on May 31, 1790. On June 9, 1790, the first copyright in the United States was registered for The Philadelphia Spelling Book by John Barry.

There are significant differences in the understanding of copyright in the English- and non-Englishspeaking world. The Napoleonic or Civil Code, the dominant legal system in the non-English-speaking world, splits the rights into two classes: the author's economic rights and the author's moral rights. Moral rights are available only to "natural persons". Legal persons (corporations) have economic rights but not moral rights.

Copyright Apache - Apache copyright notification

## Description Also see

## Description

Stata uses portions of the Apache Commons Java components library, Apache log4j Java library, the docx4j Java library, the FlatLaf Java library, the JSON.simple Java library, and Apache Batik SVG Toolkit with the express permission of the authors under the Apache License, version 2.0, pursuant to the following notice:

Apache License
Version 2.0, January 2004
http://www.apache.org/licenses/

## TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

## 1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.
"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.
"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent $(50 \%)$ or more of the outstanding shares, or (iii) beneficial ownership of such entity.
"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.
"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.
"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.
"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).
"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.
"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."
"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.
2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royaltyfree, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.
3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.
4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:
You must give any other recipients of the Work or Derivative Works a copy of this License; and

You must cause any modified files to carry prominent notices stating that You changed the files; and

You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may
add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License. You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.
5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.
6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.
7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.
8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.
9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

## END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work
To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]
Licensed under the Apache License, Version 2.0 (the "License"); you may not use this file except in compliance with the License. You may obtain a copy of the License at http://www.apache.org/licenses/LICENSE-2.0
Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

Copyright H2O — H2O copyright notification

## Description Also see

## Description

Stata uses portions of the H2O Java library with the express permission of the authors under the Apache License, version 2.0, pursuant to the following notice:

## Apache License

Version 2.0, January 2004
http://www.apache.org/licenses/

## TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.
"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.
"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.
"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50\%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.
"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.
"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.
"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.
"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).
"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.
"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."
"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.
2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royaltyfree, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.
3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.
4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:
(a) You must give any other recipients of the Work or Derivative Works a copy of this License; and
(b) You must cause any modified files to carry prominent notices stating that You changed the files; and
(c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
(d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may
add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.
5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.
6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.
7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.
8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.
9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

## END OF TERMS AND CONDITIONS

## APPENDIX: How to apply the Apache License to your work.

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets " $\}$ " replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description
of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

## Description Source code Also see

## Description

Stata uses portions of JAXB with the express permission of the authors, pursuant to the terms of the Common Development and Distribution License (CDDL) version 1.1.

## COMMON DEVELOPMENT AND DISTRIBUTION LICENSE (CDDL) Version 1.1

1. Definitions.
1.1. "Contributor" means each individual or entity that creates or contributes to the creation of Modifications.
1.2. "Contributor Version" means the combination of the Original Software, prior Modifications used by a Contributor (if any), and the Modifications made by that particular Contributor.
1.3. "Covered Software" means (a) the Original Software, or (b) Modifications, or (c) the combination of files containing Original Software with files containing Modifications, in each case including portions thereof.
1.4. "Executable" means the Covered Software in any form other than Source Code.
1.5. "Initial Developer" means the individual or entity that first makes Original Software available under this License.
1.6. "Larger Work" means a work which combines Covered Software or portions thereof with code not governed by the terms of this License.
1.7. "License" means this document.
1.8. "Licensable" means having the right to grant, to the maximum extent possible, whether at the time of the initial grant or subsequently acquired, any and all of the rights conveyed herein.
1.9. "Modifications" means the Source Code and Executable form of any of the following:
A. Any file that results from an addition to, deletion from or modification of the contents of a file containing Original Software or previous Modifications;
B. Any new file that contains any part of the Original Software or previous Modification; or
C. Any new file that is contributed or otherwise made available under the terms of this License.
1.10. "Original Software" means the Source Code and Executable form of computer software code that is originally released under this License.
1.11. "Patent Claims" means any patent claim(s), now owned or hereafter acquired, including without limitation, method, process, and apparatus claims, in any patent Licensable by grantor.
1.12. "Source Code" means (a) the common form of computer software code in which modifications are made and (b) associated documentation included in or with such code.
1.13. "You" (or "Your") means an individual or a legal entity exercising rights under, and complying with all of the terms of, this License. For legal entities, "You" includes any entity which controls, is controlled by, or is under common control with You. For purposes of this definition, "control" means (a) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (b) ownership of more than fifty percent (50\%) of the outstanding shares or beneficial ownership of such entity.

## 2. License Grants.

2.1. The Initial Developer Grant.

Conditioned upon Your compliance with Section 3.1 below and subject to third party intellectual property claims, the Initial Developer hereby grants You a world-wide, royalty-free, non-exclusive license:
(a) under intellectual property rights (other than patent or trademark) Licensable by Initial Developer, to use, reproduce, modify, display, perform, sublicense and distribute the Original Software (or portions thereof), with or without Modifications, and/or as part of a Larger Work; and
(b) under Patent Claims infringed by the making, using or selling of Original Software, to make, have made, use, practice, sell, and offer for sale, and/or otherwise dispose of the Original Software (or portions thereof).
(c) The licenses granted in Sections 2.1(a) and (b) are effective on the date Initial Developer first distributes or otherwise makes the Original Software available to a third party under the terms of this License.
(d) Notwithstanding Section 2.1(b) above, no patent license is granted: (1) for code that You delete from the Original Software, or (2) for infringements caused by: (i) the modification of the Original Software, or (ii) the combination of the Original Software with other software or devices.

### 2.2. Contributor Grant.

Conditioned upon Your compliance with Section 3.1 below and subject to third party intellectual property claims, each Contributor hereby grants You a world-wide, royalty-free, non-exclusive license:
(a) under intellectual property rights (other than patent or trademark) Licensable by Contributor to use, reproduce, modify, display, perform, sublicense and distribute the Modifications created by such Contributor (or portions thereof), either on an unmodified basis, with other Modifications, as Covered Software and/or as part of a Larger Work; and
(b) under Patent Claims infringed by the making, using, or selling of Modifications made by that Contributor either alone and/or in combination with its Contributor Version (or portions of such combination), to make, use, sell, offer for sale, have made, and/or otherwise dispose of: (1) Modifications made by that Contributor (or portions thereof); and (2) the combination of Modifications made by that Contributor with its Contributor Version (or portions of such combination).
(c) The licenses granted in Sections 2.2(a) and 2.2(b) are effective on the date Contributor first distributes or otherwise makes the Modifications available to a third party.
(d) Notwithstanding Section 2.2(b) above, no patent license is granted: (1) for any code that Contributor has deleted from the Contributor Version; (2) for infringements caused by: (i) third party modifications of Contributor Version, or (ii) the combination of Modifications made by that Contributor with other software (except as part of the Contributor Version) or other devices; or (3) under Patent Claims infringed by Covered Software in the absence of Modifications made by that Contributor.
3. Distribution Obligations.
3.1. Availability of Source Code.

Any Covered Software that You distribute or otherwise make available in Executable form must also be made available in Source Code form and that Source Code form must be distributed only under the terms of this License. You must include a copy of this License with every copy of the Source Code form of the Covered Software You distribute or otherwise make available. You must inform recipients of any such Covered Software in Executable form as to how they can obtain such Covered Software in Source Code form in a reasonable manner on or through a medium customarily used for software exchange.

### 3.2. Modifications.

The Modifications that You create or to which You contribute are governed by the terms of this License. You represent that You believe Your Modifications are Your original creation(s) and/or You have sufficient rights to grant the rights conveyed by this License.

### 3.3. Required Notices.

You must include a notice in each of Your Modifications that identifies You as the Contributor of the Modification. You may not remove or alter any copyright, patent or trademark notices contained within the Covered Software, or any notices of licensing or any descriptive text giving attribution to any Contributor or the Initial Developer.
3.4. Application of Additional Terms.

You may not offer or impose any terms on any Covered Software in Source Code form that alters or restricts the applicable version of this License or the recipients' rights hereunder. You may choose to offer, and to charge a fee for, warranty, support, indemnity or liability obligations to one or more recipients of Covered Software. However, you may do so only on Your own behalf, and not on behalf of the Initial Developer or any Contributor. You must make it absolutely clear that any such warranty, support, indemnity or liability obligation is offered by You alone, and You hereby agree to indemnify the Initial Developer and every Contributor for any liability incurred by the Initial Developer or such Contributor as a result of warranty, support, indemnity or liability terms You offer.
3.5. Distribution of Executable Versions.

You may distribute the Executable form of the Covered Software under the terms of this License or under the terms of a license of Your choice, which may contain terms different from this License, provided that You are in compliance with the terms of
this License and that the license for the Executable form does not attempt to limit or alter the recipient's rights in the Source Code form from the rights set forth in this License. If You distribute the Covered Software in Executable form under a different license, You must make it absolutely clear that any terms which differ from this License are offered by You alone, not by the Initial Developer or Contributor. You hereby agree to indemnify the Initial Developer and every Contributor for any liability incurred by the Initial Developer or such Contributor as a result of any such terms You offer.
3.6. Larger Works.

You may create a Larger Work by combining Covered Software with other code not governed by the terms of this License and distribute the Larger Work as a single product. In such a case, You must make sure the requirements of this License are fulfilled for the Covered Software.
4. Versions of the License.

### 4.1. New Versions.

Oracle is the initial license steward and may publish revised and/or new versions of this License from time to time. Each version will be given a distinguishing version number. Except as provided in Section 4.3, no one other than the license steward has the right to modify this License.

### 4.2. Effect of New Versions.

You may always continue to use, distribute or otherwise make the Covered Software available under the terms of the version of the License under which You originally received the Covered Software. If the Initial Developer includes a notice in the Original Software prohibiting it from being distributed or otherwise made available under any subsequent version of the License, You must distribute and make the Covered Software available under the terms of the version of the License under which You originally received the Covered Software. Otherwise, You may also choose to use, distribute or otherwise make the Covered Software available under the terms of any subsequent version of the License published by the license steward.
4.3. Modified Versions.

When You are an Initial Developer and You want to create a new license for Your Original Software, You may create and use a modified version of this License if You: (a) rename the license and remove any references to the name of the license steward (except to note that the license differs from this License); and (b) otherwise make it clear that the license contains terms which differ from this License.

## 5. DISCLAIMER OF WARRANTY.

COVERED SOFTWARE IS PROVIDED UNDER THIS LICENSE ON AN "AS IS" BASIS, WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, WITHOUT LIMITATION, WARRANTIES THAT THE COVERED SOFTWARE IS FREE OF DEFECTS, MERCHANTABLE, FIT FOR A PARTICULAR PURPOSE OR NON-INFRINGING. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE COVERED SOFTWARE IS WITH YOU. SHOULD ANY COVERED SOFTWARE PROVE DEFECTIVE IN ANY RESPECT, YOU (NOT THE INITIAL DEVELOPER OR ANY OTHER CONTRIBUTOR) ASSUME THE COST OF ANY NECESSARY SERVICING, REPAIR OR CORRECTION. THIS DISCLAIMER OF WARRANTY CONSTITUTES AN ESSENTIAL PART OF

THIS LICENSE. NO USE OF ANY COVERED SOFTWARE IS AUTHORIZED HEREUNDER EXCEPT UNDER THIS DISCLAIMER.
6. TERMINATION.
6.1. This License and the rights granted hereunder will terminate automatically if You fail to comply with terms herein and fail to cure such breach within 30 days of becoming aware of the breach. Provisions which, by their nature, must remain in effect beyond the termination of this License shall survive.
6.2. If You assert a patent infringement claim (excluding declaratory judgment actions) against Initial Developer or a Contributor (the Initial Developer or Contributor against whom You assert such claim is referred to as "Participant") alleging that the Participant Software (meaning the Contributor Version where the Participant is a Contributor or the Original Software where the Participant is the Initial Developer) directly or indirectly infringes any patent, then any and all rights granted directly or indirectly to You by such Participant, the Initial Developer (if the Initial Developer is not the Participant) and all Contributors under Sections 2.1 and/or 2.2 of this License shall, upon 60 days notice from Participant terminate prospectively and automatically at the expiration of such 60 day notice period, unless if within such 60 day period You withdraw Your claim with respect to the Participant Software against such Participant either unilaterally or pursuant to a written agreement with Participant.
6.3. If You assert a patent infringement claim against Participant alleging that the Participant Software directly or indirectly infringes any patent where such claim is resolved (such as by license or settlement) prior to the initiation of patent infringement litigation, then the reasonable value of the licenses granted by such Participant under Sections 2.1 or 2.2 shall be taken into account in determining the amount or value of any payment or license.
6.4. In the event of termination under Sections 6.1 or 6.2 above, all end user licenses that have been validly granted by You or any distributor hereunder prior to termination (excluding licenses granted to You by any distributor) shall survive termination.

## 7. LIMITATION OF LIABILITY.

UNDER NO CIRCUMSTANCES AND UNDER NO LEGAL THEORY, WHETHER TORT (INCLUDING NEGLIGENCE), CONTRACT, OR OTHERWISE, SHALL YOU, THE INITIAL DEVELOPER, ANY OTHER CONTRIBUTOR, OR ANY DISTRIBUTOR OF COVERED SOFTWARE, OR ANY SUPPLIER OF ANY OF SUCH PARTIES, BE LIABLE TO ANY PERSON FOR ANY INDIRECT, SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES OF ANY CHARACTER INCLUDING, WITHOUT LIMITATION, DAMAGES FOR LOSS OF GOODWILL, WORK STOPPAGE, COMPUTER FAILURE OR MALFUNCTION, OR ANY AND ALL OTHER COMMERCIAL DAMAGES OR LOSSES, EVEN IF SUCH PARTY SHALL HAVE BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. THIS LIMITATION OF LIABILITY SHALL NOT APPLY TO LIABILITY FOR DEATH OR PERSONAL INJURY RESULTING FROM SUCH PARTY'S NEGLIGENCE TO THE EXTENT APPLICABLE LAW PROHIBITS SUCH LIMITATION. SOME JURISDICTIONS DO NOT ALLOW THE EXCLUSION OR LIMITATION OF INCIDENTAL OR CONSEQUENTIAL DAMAGES, SO THIS EXCLUSION AND LIMITATION MAY NOT APPLY TO YOU.

## 8. U.S. GOVERNMENT END USERS.

The Covered Software is a "commercial item," as that term is defined in 48 C.F.R. 2.101 (Oct. 1995), consisting of "commercial computer software" (as that term is defined at 48 C.F.R. §252.227-7014(a)(1)) and "commercial computer software documentation" as such terms are used in 48 C.F.R. 12.212 (Sept. 1995). Consistent with 48 C.F.R. 12.212 and 48 C.F.R. 227.7202-1 through 227.7202-4 (June 1995), all U.S. Government End Users acquire Covered Software with only those rights set forth herein. This U.S. Government Rights clause is in lieu of, and supersedes, any other FAR, DFAR, or other clause or provision that addresses Government rights in computer software under this License.
9. MISCELLANEOUS.

This License represents the complete agreement concerning subject matter hereof. If any provision of this License is held to be unenforceable, such provision shall be reformed only to the extent necessary to make it enforceable. This License shall be governed by the law of the jurisdiction specified in a notice contained within the Original Software (except to the extent applicable law, if any, provides otherwise), excluding such jurisdiction's conflict-of-law provisions. Any litigation relating to this License shall be subject to the jurisdiction of the courts located in the jurisdiction and venue specified in a notice contained within the Original Software, with the losing party responsible for costs, including, without limitation, court costs and reasonable attorneys' fees and expenses. The application of the United Nations Convention on Contracts for the International Sale of Goods is expressly excluded. Any law or regulation which provides that the language of a contract shall be construed against the drafter shall not apply to this License. You agree that You alone are responsible for compliance with the United States export administration regulations (and the export control laws and regulation of any other countries) when You use, distribute or otherwise make available any Covered Software.

## 10. RESPONSIBILITY FOR CLAIMS.

As between Initial Developer and the Contributors, each party is responsible for claims and damages arising, directly or indirectly, out of its utilization of rights under this License and You agree to work with Initial Developer and Contributors to distribute such responsibility on an equitable basis. Nothing herein is intended or shall be deemed to constitute any admission of liability.

## Source code

Per Section 3.1 above, the source code for JAXB is publicly available via https://javaee.github.io/ jaxb-v2/.

## Title

correlate - Correlations of variables

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options for correlate | Options for pwcorr | Remarks and examples | Stored results |
| Methods and formulas | References | Also see |  |

## Description

The correlate command displays the correlation matrix or covariance matrix for a group of variables. If varlist is not specified, the matrix is displayed for all variables in the dataset.
pwcorr displays all the pairwise correlation coefficients between the variables in varlist or, if varlist is not specified, all the variables in the dataset.

## Quick start

Correlation matrix for variables v1, v2, and v3
correlate v1 v2 v3
Same as above, but display covariances instead of correlations
correlate v1 v2 v3, covariance
Pairwise correlation coefficients between v1, v2, and v3
pwcorr v1 v2 v3
Also print significance level of each correlation coefficient
pwcorr v1 v2 v3, sig
Same as above, but star correlation coefficients significant at the 5\% level
pwcorr v1 v2 v3, sig star(.05)
Same as above, but use Bonferroni-adjusted significance levels
pwcorr v1 v2 v3, sig star(.05) bonferroni

## Menu

## correlate

Statistics $>$ Summaries, tables, and tests $>$ Summary and descriptive statistics $>$ Correlations and covariances

## pwcorr

Statistics $>$ Summaries, tables, and tests $>$ Summary and descriptive statistics $>$ Pairwise correlations

## Syntax

Display correlation matrix or covariance matrix
correlate $[$ varlist $][$ if $][$ in $][$ weight $][$, correlate_options $]$

Display all pairwise correlation coefficients

```
pwcorr [varlist] [if] [in] [weight] [, pwcorr_options]
```

correlate_options Description
Options
means display means, standard deviations, minimums, and maximums with matrix
noformat ignore display format associated with variables
covariance
display covariances
wrap
allow wide matrices to wrap
pwcorr_options Description
Main
obs
print number of observations for each entry
sig
listwise
casewise
print(\#)
star(\#)
bonferroni
sidak
print significance level for each entry
use listwise deletion to handle missing values
synonym for listwise
significance level for displaying coefficients
significance level for displaying with a star
use Bonferroni-adjusted significance level
use Šidák-adjusted significance level
varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists. by and collect are allowed with correlate and pwcorr; see [U] 11.1.10 Prefix commands. aweights and fweights are allowed; see [U] 11.1.6 weight.

## Options for correlate

$\square$ Options
means displays summary statistics (means, standard deviations, minimums, and maximums) with the matrix.
noformat displays the summary statistics requested by the means option in g format, regardless of the display formats associated with the variables.
covariance displays the covariances rather than the correlation coefficients.
wrap requests that no action be taken on wide correlation matrices to make them readable. It prevents Stata from breaking wide matrices into pieces to enhance readability. You might want to specify this option if you are displaying results in a window wider than 80 characters. Then you may need to set linesize to however many characters you can display across a line; see $[R] \log$.

## Options for pwcorr

$\qquad$ Main
obs adds a line to each row of the matrix reporting the number of observations used to calculate the correlation coefficient.
sig adds a line to each row of the matrix reporting the significance level of each correlation coefficient.
listwise handles missing values through listwise deletion, meaning that the entire observation is omitted from the estimation sample if any of the variables in varlist is missing for that observation. By default, pwcorr handles missing values by pairwise deletion; all available observations are used to calculate each pairwise correlation without regard to whether variables outside that pair are missing.
correlate uses listwise deletion. Thus, listwise allows users of pwcorr to mimic correlate's treatment of missing values while retaining access to pwcorr's features.
casewise is a synonym for listwise.
print(\#) specifies the significance level of correlation coefficients to be printed. Correlation coefficients with larger significance levels are left blank in the matrix. Typing pwcorr, print (.10) would list only correlation coefficients significant at the $10 \%$ level or better.
star(\#) specifies the significance level of correlation coefficients to be starred. Typing pwcorr, star (.05) would star all correlation coefficients significant at the $5 \%$ level or better.
bonferroni makes the Bonferroni adjustment to calculated significance levels. This option affects printed significance levels and the print() and star() options. Thus, pwcorr, print(.05) bonferroni prints coefficients with Bonferroni-adjusted significance levels of 0.05 or less.
sidak makes the Šidák adjustment to calculated significance levels. This option affects printed significance levels and the print() and star() options. Thus, pwcorr, print(.05) sidak prints coefficients with Šidák-adjusted significance levels of 0.05 or less.

## Remarks and examples

Remarks are presented under the following headings:

```
correlate
pwcorr
Video example
```

## correlate

Typing correlate by itself produces a correlation matrix for all variables in the dataset. If you specify the varlist, a correlation matrix for just those variables is displayed.

## > Example 1

We have state data on demographic characteristics of the population. To obtain a correlation matrix, we type

|  | state | brate | pop | medage | division | region | mrgrate |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| state | 1.0000 |  |  |  |  |  |  |
| brate | 0.0208 | 1.0000 |  |  |  |  |  |
| pop | -0.0540 | -0.2830 | 1.0000 |  |  |  |  |
| medage | -0.0624 | -0.8800 | 0.3294 | 1.0000 |  |  |  |
| division | -0.1345 | 0.6356 | -0.1081 | -0.5207 | 1.0000 |  |  |
| region | -0.1339 | 0.6086 | -0.1515 | -0.5292 | 0.9688 | 1.0000 |  |
| mrgrate | 0.0509 | 0.0677 | -0.1502 | -0.0177 | 0.2280 | 0.2490 | 1.0000 |
| dvcrate | -0.0655 | 0.3508 | -0.2064 | -0.2229 | 0.5522 | 0.5682 | 0.7700 |
| medagesq | -0.0621 | -0.8609 | 0.3324 | 0.9984 | -0.5162 | -0.5239 | -0.0202 |
| dvcrate medagesq |  |  |  |  |  |  |  |
| dvcrate | 1.0000 |  |  |  |  |  |  |
| medagesq | -0.2192 | 1.0000 |  |  |  |  |  |

Because we did not specify the wrap option, Stata did its best to make the result readable by breaking the table into two parts.

To obtain the correlations between mrgrate, dvcrate, and medage, we type

```
. correlate mrgrate dvcrate medage
(obs=50)
```

|  | mrgrate | dvcrate | medage |
| ---: | ---: | ---: | ---: |
| mrgrate | 1.0000 |  |  |
| dvcrate | 0.7700 | 1.0000 |  |
| medage | -0.0177 | -0.2229 | 1.0000 |

## Example 2

The pop variable in example 1 represents the total population of the state. Thus, to obtain population-weighted correlations among mrgrate, dvcrate, and medage, we type

```
. correlate mrgrate dvcrate medage [w=pop]
(analytic weights assumed)
(sum of wgt is 225,907,472)
(obs=50)
\begin{tabular}{r|rrr} 
& mrgrate & dvcrate & medage \\
\hline mrgrate & 1.0000 & & \\
dvcrate & 0.5854 & 1.0000 & \\
medage & -0.1316 & -0.2833 & 1.0000
\end{tabular}
```

With the covariance option, correlate can be used to obtain covariance matrices, as well as correlation matrices, for both weighted and unweighted data.

## > Example 3

To obtain the matrix of covariances between mrgrate, dvcrate, and medage, we type correlate mrgrate dvcrate medage, covariance:

```
. correlate mrgrate dvcrate medage, covariance
(obs=50)
\begin{tabular}{r|rrr} 
& mrgrate & dvcrate & medage \\
\hline mrgrate & .000662 & & \\
dvcrate & .000063 & \(1.0 \mathrm{e}-05\) & \\
medage & -.000769 & -.001191 & 2.86775
\end{tabular}
```

We could have obtained the pop-weighted covariance matrix by typing correlate mrgrate dvcrate medage [w=pop], covariance.

## pwcorr

correlate calculates correlation coefficients by using casewise deletion; when you request correlations of variables $x_{1}, x_{2}, \ldots, x_{k}$, any observation for which any of $x_{1}, x_{2}, \ldots, x_{k}$ is missing is not used. Thus if $x_{3}$ and $x_{4}$ have no missing values, but $x_{2}$ is missing for half the data, the correlation between $x_{3}$ and $x_{4}$ is calculated using only the half of the data for which $x_{2}$ is not missing. Of course, you can obtain the correlation between $x_{3}$ and $x_{4}$ by using all the data by typing correlate $x_{3} x_{4}$. pwcorr makes obtaining such pairwise correlation coefficients easier.

## > Example 4

Using auto.dta, we investigate the correlation between several of the variables.

|  | mpg | price | headroom r | rear_s ${ }^{\sim}$ t | trunk | rep78 | foreign |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| mpg | 1.0000 |  |  |  |  |  |  |
| price | -0.4594* | 1.0000 |  |  |  |  |  |
| headroom | -0.4220* |  | 1.0000 |  |  |  |  |
| rear_seat | -0.5213* | 0.4194* | 0.5238* | 1.0000 |  |  |  |
| trunk | -0.5703* | 0.3143* | 0.6620* | 0.6480* | 1.0000 |  |  |
| rep78 | 0.3739* |  |  |  |  | 1.0000 |  |
| foreign | 0.3613* |  | -0.2939 | -0.2409 | -0.3594* | 0.5922* | 1.0000 |
| pwcorr mpg price headroom rear_seat trunk rep78 foreign, print(.05) bon mpg price headroom rear_s $\sim$ t trunk rep78 foreign |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |
| mpg | 1.0000 |  |  |  |  |  |  |
| price | -0.4594 | 1.0000 |  |  |  |  |  |
| headroom | -0.4220 | 1.0000 |  |  |  |  |  |
| rear_seat | -0.5213 | 0.4194 | 0.5238 | 1.0000 |  |  |  |
| trunk | -0.5703 |  | 0.6620 | 0.6480 | 1.0000 |  |  |
| rep78 | 0.3739 |  |  |  |  | 1.0000 |  |
| foreign | 0.3613 |  |  |  | -0.3594 | 0.5922 | 1.0000 |

## Technical note

The correlate command will report the correlation matrix of the data, but there are occasions when you need the matrix stored as a Stata matrix so that you can further manipulate it. You can obtain the matrix by typing
. matrix accum $\mathrm{R}=$ varlist, noconstant deviations
. matrix $R=\operatorname{corr}(R)$
The first line places the cross-product matrix of the data in matrix R . The second line converts that to a correlation matrix. Also see $[\mathrm{P}]$ matrix define and $[\mathrm{P}]$ matrix accum.

## Video example

Pearson's correlation coefficient in Stata

## Stored results

correlate stores the following in r() :
Scalars
$r(N) \quad$ number of observations
$r$ (rho) $\quad \rho$ (first and second variables)
r(cov_12) covariance (covariance only)
$r$ (Var_1) variance of first variable (covariance only)
$r$ (Var_2) variance of second variable (covariance only)
r(sum_w) sum of weights
Matrices
$r$ (C) correlation or covariance matrix
pwcorr stores the following in $r()$ :
Scalars
$r(N) \quad$ number of observations (first and second variables)
$r$ (rho) $\quad \rho$ (first and second variables)
Matrices
$r$ (Nobs) number of observations for each correlation coefficient
r(C) pairwise correlation matrix
r(sig) significance level of each correlation coefficient

## Methods and formulas

For a discussion of correlation, see, for instance, Snedecor and Cochran (1989, 177-195); for an introductory explanation using Stata examples, see Acock (2023, 205-210).

According to Snedecor and Cochran (1989, 180), the term "co-relation" was first proposed by Galton (1888). The product-moment correlation coefficient is often called the Pearson product-moment correlation coefficient because Pearson (1896) and Pearson and Filon (1898) were partially responsible for popularizing its use. See Stigler (1986) for information on the history of correlation.

The estimate of the product-moment correlation coefficient, $\rho$, is

$$
\widehat{\rho}=\frac{\sum_{i=1}^{n} w_{i}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\sqrt{\sum_{i=1}^{n} w_{i}\left(x_{i}-\bar{x}\right)^{2}} \sqrt{\sum_{i=1}^{n} w_{i}\left(y_{i}-\bar{y}\right)^{2}}}
$$

where $w_{i}$ are the weights, if specified, or $w_{i}=1$ if weights are not specified. $\bar{x}=\left(\sum w_{i} x_{i}\right) /\left(\sum w_{i}\right)$ is the mean of $x$, and $\bar{y}$ is similarly defined.

The unadjusted significance level is calculated by pwcorr as

$$
p=2 * \operatorname{ttail}\left(n-2,|\widehat{\rho}| \sqrt{n-2} / \sqrt{1-\widehat{\rho}^{2}}\right)
$$

Let $v$ be the number of variables specified so that $k=v(v-1) / 2$ correlation coefficients are to be estimated. If bonferroni is specified, the adjusted significance level is $p^{\prime}=\min (1, k p)$. If sidak is specified, $p^{\prime}=\min \left\{1,1-(1-p)^{k}\right\}$. In both cases, see Methods and formulas in [R] oneway for a more complete description of the logic behind these adjustments.

Carlo Emilio Bonferroni (1892-1960) was born in Bergamo, Italy, in 1892. Before enrolling in the mathematics department at the University of Turin, he studied conducting and the piano at the Music Conservatory of Turin. Bonferroni, like many men of his generation, fought in World War I, during which he was part of The Engineer Corps of the Italian Army.

After the war, Bonferroni was appointed as an assistant professor at the Polytechnic University of Turin. He taught geometry, mechanics, and analysis. In 1923, he moved to Bari and began teaching at the Economics Institute, where he got to teach financial mathematics, a topic that was of great interest to him. In 1933, Bonferroni moved to Florence, where he was chair of the mathematics department until his death in 1960.
Bonferroni's interests had a large breadth. He published on actuarial mathematics, probability, statistics, analysis, geometry, and mechanics. His work on probability inequalities has been applied to simultaneous statistical inference. However, the application of Bonferroni's theory to the construction of confidence intervals is the work of Olive Jean Dunn.

Olive Jean Dunn (1915-2008) was born in the United States in 1915. She obtained her bachelor's degree in 1936, her master's degree in 1951, and her PhD in 1956, all from the University of California in Los Angeles (UCLA). After spending one year as an assistant professor at Iowa State College, she returned to UCLA to serve in the biostatistics and preventive medicine and health departments. She remained at UCLA for the rest of her career. Dunn died in 2008.

Dunn is best known for her application of Bonferroni's inequalities to construct corrections to confidence intervals for multiple comparisons. Although the literature refers to it as the Bonferroni correction, it is Dunn who developed the application we use today.

Dunn is also well known for her textbooks Basic Statistics: A Primer for the Biomedical Sciences, written in 1977 with later editions coauthored with Virginia A. Clark, and Applied Statistics: An Analysis of Variance and Regression, which was also coauthored with Clark.

In 1968, Dunn became a Fellow of the American Statistical Association. She also was a fellow of the American Public Health Association and the American Association for the Advancement of Science. In 1974, she was awarded the honor of UCLA Woman of Science.

Florence Nightingale David (1909-1993) was born in Ivington, England, to parents who were friends with Florence Nightingale, David's namesake. She began her studies in statistics under the direction of Karl Pearson at University College London and continued her studies under the direction of Jerzy Neyman. After receiving her doctorate in statistics in 1938, David became a senior statistician for various departments within the British military. She developed statistical models to forecast the toll on life and infrastructure that would occur if a large city were bombed. In 1938, she also published her book Tables of the Correlation Coefficient, dealing with the distributions of correlation coefficients. After the war, she returned to University College London, serving as a lecturer until her promotion to professor in 1962. In 1967, David joined the University of California-Riverside, eventually becoming chair of the Department of Statistics. One of her most well-known works is the book Games, Gods and Gambling: The Origins and History of Probability and Statistical Ideas from the Earliest Times to the Newtonian Era, a history of statistics. David published over 100 papers on topics including combinatorics, symmetric functions, the history of statistics, and applications of statistics, including ecological diversity. She published under the name F. N. David to avoid revealing her gender in a male-dominated profession.

Karl Pearson (1857-1936) studied mathematics at Cambridge. He was professor of applied mathematics (1884-1911) and eugenics (1911-1933) at University College London. His publications include literary, historical, philosophical, and religious topics. Statistics became his main interest in the early 1890s after he learned about its application to biological problems. His work centered on distribution theory, the method of moments, correlation, and regression. Pearson introduced the $\chi^{2}$ test and the terms coefficient of variation, contingency table, heteroskedastic, histogram, homoskedastic, kurtosis, mode, random sampling, random walk, skewness, standard deviation, and truncation. Despite many strong qualities, he also fell into prolonged disagreements with others, most notably, William Bateson and R. A. Fisher.

Zbyněk Šidák (1933-1999) was a notable Czech statistician and probabilist. He worked on Markov chains, rank tests, multivariate distribution theory and multiple-comparison methods, and he served as the chief editor of Applications of Mathematics.

## Title

cpoisson - Censored Poisson regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

cpoisson fits a Poisson model of a count dependent variable with some censored values. The command can be used when the dependent variable is left-censored (has a lower limit), is right-censored (has an upper limit), or is interval-censored (has a lower and an upper limit).

## Quick start

Censored Poisson regression of y on x without options 11 () and ul (), equivalent to Poisson regression cpoisson y x

Add categorical variable a using factor-variable syntax, and specify censoring at an upper limit of 4 cpoisson y x i.a, ul(4)

Also specify a lower-censoring limit that varies across observations by using the variable lower cpoisson y x i.a, ul(4) ll(lower)

Add offset variable v , and report results as incidence-rate ratios
cpoisson y x i.a, ul(4) ll(lower) offset(v) irr
Constrain the coefficient for x to 2
constraint define $1 \mathrm{x}=2$
cpoisson y x i.a, ul(4) constraints(1)

## Menu

exposure (varname $_{e}$ )
offset (varname ${ }_{o}$ )
constraints (constraints)
SE/Robust
vce (vcetype)

Reporting
level(\#)
irr
nocnsreport
display_options

Description
suppress constant term
left-censoring variable or limit
right-censoring variable or limit
include $\ln \left(\right.$ varname $\left._{e}\right)$ in model with coefficient constrained to 1 include varname ${ }_{o}$ in model with coefficient constrained to 1 apply specified linear constraints
vcetype may be oim, robust, cluster clustvar, bootstrap, or jackknife
set confidence level; default is level (95)
report incidence-rate ratios
do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
control the maximization process; seldom used
keep collinear variables
display legend instead of statistics

Maximization
maximize_options
collinear
coeflegend
indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

$\qquad$ Model

## noconstant; see [R] Estimation options.

$11[($ varname $\mid \#)]$ and $u l[$ (varname $\mid \#)]$ indicate the lower and upper limits for censoring, respectively. Observations with depvar $\leq 11$ () are left-censored; observations with depvar $\geq \mathrm{ul}$ () are right-censored; and remaining observations are not censored. You do not have to specify the censoring values. If you specify 11 , the lower limit is the minimum of depvar. If you specify $u l$, the upper limit is the maximum of depvar.
exposure ( varname $_{e}$ ), offset ( varname $_{o}$ ), constraints (constraints); see [R] Estimation options.

## SE/Robust

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

## Reporting

level(\#); see [R] Estimation options.
irr reports estimated coefficients transformed to incidence-rate ratios, that is, $e^{\beta_{i}}$ rather than $\beta_{i}$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. irr may be specified at estimation or when replaying previously estimated results.
nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% fmt), and nolstretch; see [R] Estimation options.

Maximization
maximize_options: difficult, technique (algorithm_spec), iterate (\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance(\#), nonrtolerance, and from (init_specs); see [R] Maximize. These options are seldom used.

The following options are available with cpoisson but are not shown in the dialog box:
collinear, coeflegend; see [R] Estimation options.

## Remarks and examples

Censored Poisson regression is a method for analyzing censored count data. One of the most common sources of censored count data is top coding, data that record only the value $x$ when $x$ or greater is observed. Not observing subjects for a sufficient period of time is another common cause.

Censored count data models have been studied by Terza (1985) and Brännäs (1992), among others. For an introduction to censored Poisson regression, see Cameron and Trivedi $(2005,2013)$ and Winkelmann (2008). Raciborski (2011) discusses a command for right-censored Poisson regression and presented Monte Carlo results indicating that the estimator performs well in finite samples. See Creel and Loomis (1990) and Gurmu and Trivedi (1996) for some examples of survey applications with top coding.

Censored data can be right-censored, left-censored, or interval-censored. Right-censoring occurs when we observe the covariates but only observe that the dependent variable is greater than or equal to an upper limit. Left-censoring occurs when we observe the covariates but only observe that the dependent variable is less than or equal to a lower limit.

When the dependent variable is censored, we must use estimation methods that account for this limitation. If we do not account for censoring when our data are censored, our estimates will not converge to the true values. More formally, failure to control for censoring when it exists leads to inconsistent parameter estimation.

Censored Poisson regression provides an alternative to standard Poisson regression that produces consistent estimates when the dependent variable is censored. If the dependent variable is not censored, standard Poisson regression may be more appropriate; see $[R]$ poisson.

Censoring differs from truncation. For censored observations, we observe complete covariate information but only a censored value of the dependent variable. When the data are truncated, we do not observe either the dependent variable or the covariates. Different research designs can give rise to censored data or truncated data.

For example, consider a study about the use of national parks. We could ask a random sample of people in the population how many national parks each has visited in the past year. Suppose we decide to record three for those individuals who visited three or more parks. In this case, individuals who visit four or more parks will have observations that are right-censored at three visits. Now suppose that instead of sending out surveys to a random sample from the population, we ask questions only of individuals who come to parks. We will have no information about individuals who do not visit at least one park, and the data will be truncated at zero visits.

Censoring and truncation are different statistical phenomenon and require different analytic methods. See [R] tpoisson for information on truncated Poisson regression.

## > Example 1: Poisson model with top-coded data

Imagine that we have collected survey data about how many times a household has visited the ABC amusement park from a random sample of households in the state in which ABC is located. Respondents were asked about the number of visits to the park in the last year (trips), their income (income), and the number of children in the household (children). The number of trips recorded in trips was top coded at "three or more" visits.

We model right-censored trips as a function of income and children.

| (Visits to the ABC amusement park) <br> . cpoisson trips income children, ul(3) |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Initial: Log likelihood $=-620.68749$ |  |  |  |  |  |  |
| Rescale: Log likelihood $=-620.68749$ |  |  |  |  |  |  |
| Iteration 0: Log likelihood $=-620.68749$ |  |  |  |  |  |  |
| Iteration 1: Log likelihood $=-600.96763$ |  |  |  |  |  |  |
| Iteration 2: Log likelihood $=-600.78416$ |  |  |  |  |  |  |
| Iteration 3: Log likelihood = -600.78415 |  |  |  |  |  |  |
| Censored Poisson regression |  |  |  |  | r of obs | $=500$ |
|  |  |  |  |  | Uncensored | $=278$ |
| Limits: Lower $=0$ |  |  |  |  | Left-censored | $=0$ |
| Upper $=3$ |  |  |  |  | ght-censored | 222 |
|  |  |  |  |  | i2(2) | $=49.29$ |
| Log likelihood = -600.78415 |  |  |  |  | > chi2 | $=0.0000$ |
| trips | Coefficient | Std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. | interval] |
| income | . 0740477 | . 0137653 | 5.38 | 0.000 | . 0470683 | . 1010272 |
| children | . 1346922 | . 028617 | 4.71 | 0.000 | . 078604 | . 1907805 |
| _cons | . 0033918 | . 1455473 | 0.02 | 0.981 | -. 2818756 | . 2886592 |

Both income and the number of children have positive effects on the expected number of trips to the amusement park. The estimated parameters provide the sign, but not the magnitude of the effect, because the model is nonlinear; see $[R]$ cpoisson postestimation.

## Stored results

predictions disallowed by margins
factor variables fvset as asbalanced
factor variables fvset as asobserved
coefficient vector
constraints matrix
iteration $\log$ (up to 20 iterations)
gradient vector
variance-covariance matrix of the estimators
model-based variance
marks estimation sample

In addition to the above, the following is stored in r() :
Matrices
$r$ (table) matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

We let $y_{j}$ be the observed, interval-censored dependent variable for observation $j$ and let $y_{j}^{*}$ be the uncensored, latent dependent variable. When $y_{j}$ is not censored, it is the same as $y_{j}^{*}$. When $y_{j}$ is censored, only the censoring point is observed. Letting $L_{j}$ denote the left-censoring point (lower limit) and $U_{j}$ denote the right-censoring point (upper limit), we see that

$$
y_{j}= \begin{cases}L_{j} & \text { if } y_{j}^{*} \leq L_{j} \\ y_{j}^{*} & \text { if } L_{j}<y_{j}^{*}<U_{j} \\ U_{j} & \text { if } y_{j}^{*} \geq U_{j}\end{cases}
$$

Note that $L_{j}$ and $U_{j}$ may vary over the observations so that individuals may have different left- and right-censoring points.

Although cpoisson may be used with data that are left-censored, right-censored, or censored from both sides (which is known as interval-censored), we present the formulas for the interval-censored case because it applies to all three cases.

Let $f\left(y_{j} \mid \mathbf{x}_{j}\right)$ denote the probability mass function of the Poisson distribution. Defining $\xi_{j}=\mathbf{x}_{j} \boldsymbol{\beta}+$ offset $_{j}$ implies that the conditional mean of the uncensored variable is given by $E\left(y_{j}^{*} \mid \mathbf{x}_{j}\right)=\exp \left(\xi_{j}\right)$. The log likelihood for observation $j$ is given by

$$
l_{j}=w_{j}\left[d_{j}\left\{-\exp \left(\xi_{j}\right)+y_{j} \xi_{j}-\ln \left(y_{j}!\right)\right\}+\left(1-d_{j}\right) \ln \left\{1-\sum_{k=0}^{U_{j}-1} f\left(k \mid \mathbf{x}_{j}\right)+\sum_{k=0}^{L_{j}} f\left(k \mid \mathbf{x}_{j}\right)\right\}\right]
$$

where $d_{j}$ equals 1 when $L_{j}<y_{j}^{*}<U_{j}$ and equals 0 when $y_{j}^{*} \leq L_{j}$ or $y_{j}^{*} \geq U_{j}$. The log likelihood is thus

$$
\ln L=\sum_{j=1}^{N} l_{j}
$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce (robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.
cpoisson also supports estimation with survey data. For details on variance-covariance estimates with survey data, see [SVY] Variance estimation.

| score | first derivative of the log likelihood with respect to $\mathbf{x}_{j} \boldsymbol{\beta}$ |

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

## Options for predict

$\qquad$ Main
n , the default, calculates the predicted number of events, which is $\exp \left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$ if neither offset () nor exposure() was specified when the model was fit; $\exp \left(\mathbf{x}_{j} \boldsymbol{\beta}+\right.$ offset $\left._{j}\right)$ if offset () was specified; or $\exp \left(\mathbf{x}_{j} \boldsymbol{\beta}\right) \times$ exposure $_{j}$ if exposure() was specified.
ir calculates the incidence rate $\exp \left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$, which is the predicted number of events when exposure is 1 . This is equivalent to specifying both the n and the nooffset options.
cm calculates the conditional mean,

$$
E\left(y_{j} \mid \Omega_{j}\right)=\frac{E\left(y_{j}\right)}{\operatorname{Pr}\left(\Omega_{j}\right)}
$$

where $\Omega_{j}$ represents $y_{j}>L_{j}$ for a left-censored model, $y_{j}<U_{j}$ for a right-censored model, and $L_{j}<y_{j}<U_{j}$ for an interval-censored model. $L_{j}$ is the left-censoring point found in e(llopt), and $U_{j}$ is the right-censoring point found in e(ulopt).
$\operatorname{pr}(n)$ calculates the probability $\operatorname{Pr}\left(y_{j}=n\right)$, where $n$ is a nonnegative integer that may be specified as a number or a variable.
$\operatorname{pr}(a, b)$ calculates the probability $\operatorname{Pr}\left(a \leq y_{j} \leq b\right)$, where $a$ and $b$ are nonnegative integers that may be specified as numbers or variables;
$b$ missing ( $b \geq$.) means $+\infty$;
$\operatorname{pr}(20,$.$) calculates \operatorname{Pr}\left(y_{j} \geq 20\right)$;
$\operatorname{pr}(20, b)$ calculates $\operatorname{Pr}\left(y_{j} \geq 20\right)$ in observations for which $b \geq$. and calculates
$\operatorname{Pr}\left(20 \leq y_{j} \leq b\right)$ elsewhere.
$\operatorname{pr}(., b)$ produces a syntax error. A missing value in an observation of the variable $a$ causes a missing value in that observation for $\operatorname{pr}(a, b)$.
$\mathrm{cpr}(n)$ calculates the conditional probability $\operatorname{Pr}\left(y_{j}=n \mid \Omega_{j}\right)$, where $\Omega_{j}$ represents $y_{j}>L_{j}$ for a left-censored model, $y_{j}<U_{j}$ for a right-censored model, and $L_{j}<y_{j}<U_{j}$ for an intervalcensored model. $L_{j}$ is the left-censoring point found in e(llopt), and $U_{j}$ is the right-censoring point found in e(ulopt). $n$ is an integer in the noncensored range.
$\operatorname{cpr}(a, b)$ calculates the conditional probability $\operatorname{Pr}\left(a \leq y_{j} \leq b \mid \Omega_{j}\right)$, where $\Omega_{j}$ represents $y_{j}>L_{j}$ for a left-censored model, $y_{j}<U_{j}$ for a right-censored model, and $L_{j}<y_{j}<U_{j}$ for an intervalcensored model. $L_{j}$ is the left-censoring point found in e(llopt), and $U_{j}$ is the right-censoring point found in e (ulopt). $a$ and $b$ must fall in the noncensored range if they are not missing. A missing value in an observation of the variable $a$ causes a missing value in that observation for $\operatorname{cpr}(a, b)$.
xb calculates the linear prediction, which is $\mathbf{x}_{j} \boldsymbol{\beta}$ if neither offset () nor exposure() was specified when the model was fit; $\mathbf{x}_{j} \boldsymbol{\beta}+$ offset $_{j}$ if offset() was specified; or $\mathbf{x}_{j} \boldsymbol{\beta}+\ln \left(\operatorname{exposure}_{j}\right)$ if exposure() was specified; see nooffset below.
stdp calculates the standard error of the linear prediction.
score calculates the equation-level score, $\partial \ln L / \partial\left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$.
nooffset is relevant only if you specified offset() or exposure() when you fit the model. It modifies the calculations made by predict so that they ignore the offset or exposure variable; the linear prediction is treated as $\mathbf{x}_{j} \boldsymbol{\beta}$ rather than as $\mathbf{x}_{j} \boldsymbol{\beta}+$ offset $_{j}$ or $\mathbf{x}_{j} \boldsymbol{\beta}+\ln \left(\right.$ exposure $\left._{j}\right)$. Specifying predict..., nooffset is equivalent to specifying predict..., ir.

## margins

## Description for margins

margins estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, and linear predictions.

| cm | conditional mean, $E\left(y_{j} \mid y_{j}>L_{j}\right), E\left(y_{j} \mid y_{j}<U_{j}\right)$, <br> or $E\left(y_{j} \mid L_{j}<y_{j}<U_{j}\right)$ |
| $\operatorname{pr}(n)$ | probability $\operatorname{Pr}\left(y_{j}=n\right)$ <br> $\operatorname{pr}(a, b)$ <br> $\operatorname{probability~} \operatorname{Pr}\left(a \leq y_{j} \leq b\right)$ <br> conditional probability $\operatorname{Pr}\left(y_{j}=n \mid y_{j}>L_{j}\right), \operatorname{Pr}\left(y_{j}=n \mid y_{j}<U_{j}\right)$, <br> $\quad$ or $\operatorname{Pr}\left(y_{j}=n \mid L_{j}<y_{j}<U_{j}\right)$ |
| $\operatorname{cpr}(a, b)$ | conditional probability $\operatorname{Pr}\left(a \leq y_{j} \leq b \mid y_{j}>L_{j}\right), \operatorname{Pr}\left(a \leq y_{j} \leq b \mid y_{j}<U_{j}\right)$, <br> or $\operatorname{Pr}\left(a \leq y_{j} \leq b \mid L_{j}<y_{j}<U_{j}\right)$ |
| xb | linear prediction <br> stdp |
| not allowed with margins |  |
| score | not allowed with margins |

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

## Remarks and examples

> Example 1: Obtaining marginal effects
Continuing with example 1 of $[\mathrm{R}]$ cpoisson, we estimate the effect of having another child on the uncensored number of trips to amusement parks. We use margins to estimate the average number of trips when each household has its actual number of children and when each household has one additional child. We include the post option so that we can use the results in subsequent commands.

```
. use https://www.stata-press.com/data/r18/trips
(Visits to the ABC amusement park)
. cpoisson trips income children, ul(3)
    (output omitted)
```

```
. margins, at(children = generate(children))
> at(children = generate(children+1)) post
Predictive margins Number of obs = 500
Model VCE: OIM
Expression: Predicted number of events, predict()
1._at: children = children
2._at: children = children+1
```

|  | Delta-method <br> std. err. |  |  |  | z | $\mathrm{P}>\|\mathrm{z}\|$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Margin | [95\% conf. interval] |  |  |  |  |  |
| _at |  |  |  |  |  |  |
| 1 | 2.525517 | .0836237 | 30.20 | 0.000 | 2.361618 | 2.689417 |
| 2 | 2.889658 | .1337997 | 21.60 | 0.000 | 2.627416 | 3.151901 |

An average of 2.53 trips are taken when each household has its observed number of children. If each household has one additional child, then the average number of trips increases to 2.89 .

We now use contrast to compute the effect of having an additional child. The Wald test, in this case, is superfluous, so we suppress it with the nowald option.

```
. contrast r._at, nowald
Contrasts of predictive margins Number of obs = 500
Model VCE: OIM
Expression: Predicted number of events, predict()
1._at: children = children
2._at: children = children+1
```

|  | Delta-method <br> std. err. |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Contrast | [95\% conf. interval] |  |  |  |
| (2 vs 1) at | .3641407 | .0849951 | .1975535 | .530728 |

Adding one child to each household increases the average by 0.36 trips.

## Methods and formulas

Using the notation under Methods and formulas of $[R]$ cpoisson, we see that the equation-level score is given by

$$
\begin{aligned}
\operatorname{score}(\mathbf{x} \boldsymbol{\beta})_{j}= & d_{j}\left\{-\exp \left(\xi_{j}\right)+y_{j}\right\} \\
& +\left(1-d_{j}\right) \frac{\Psi_{1}\left(L_{j} \mid \mathbf{x}_{j}\right)-\Psi_{1}\left(U_{j}-1 \mid \mathbf{x}_{j}\right)}{1-F\left(U_{j}-1 \mid \mathbf{x}_{j}\right)+F\left(L_{j} \mid \mathbf{x}_{j}\right)}
\end{aligned}
$$

where $\Psi_{1}(C)=\sum_{k=0}^{C} f\left(k \mid \mathbf{x}_{j}\right)\left\{k-\exp \left(\xi_{j}\right)\right\} ; f\left(y_{j} \mid \mathbf{x}_{j}\right)$ and $F\left(y_{j} \mid \mathbf{x}_{j}\right)$ denote the probability mass function and the cumulative distribution function of the Poisson, respectively. $L_{j}$ is the left-censoring point found in e(llopt), and $U_{j}$ is the right-censoring point found in e(ulopt).

## Title

cumul - Cumulative distribution

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Acknowledgment | References |
| Also see |  |  |  |

## Description

cumul creates newvar, defined as the empirical cumulative distribution function of varname.

## Quick start

Create new variable ecd containing the empirical cumulative distribution of v cumul v, gen(ecd)

Use frequency as the unit for $v$ to generate ecdf
cumul v, gen(ecdf) freq
Give equal values of $v$ the same value in generated ecde
cumul v, gen(ecde) equal
Graph the empirical cumulative distribution of $v$
line ecd v, sort
Graph the distributions of variables v1 and v2
cumul v1, gen(ecd1) equal
cumul v2, gen(ecd2) equal
stack ecd1 v1 ecd2 v2, into(ecd v) wide clear
line ecd1 ecd2 v, sort

## Menu

Statistics $>$ Summaries, tables, and tests $>$ Distributional plots and tests $>$ Generate cumulative distribution

## Syntax

cumul varname $[$ if $][$ in $]$ [weight], generate(newvar) [options]
options
Description
Main

| * generate (newvar) | create variable newvar |
| :--- | :--- |
| freq | use frequency units for cumulative |
| equal | generate equal cumulatives for tied values |

* generate (newvar) is required.
by is allowed; see [D] by.
fweights and aweights are allowed; see [U] 11.1.6 weight.

## Options

$\qquad$ Main
generate (newvar) is required. It specifies the name of the new variable to be created.
freq specifies that the cumulative be in frequency units; otherwise, it is normalized so that newvar
is 1 for the largest value of varname.
equal requests that observations with equal values in varname get the same cumulative value in newvar.

## Remarks and examples

## Example 1

cumul is most often used with graph to graph the empirical cumulative distribution. For instance, we have data on the median family income of 957 US cities:

```
. use https://www.stata-press.com/data/r18/hsng
(1980 Census housing data)
. cumul faminc, gen(cum)
. sort cum
. line cum faminc, ytitle("") xlabel(, format(%6.Of))
> title("Cumulative of median family income")
> subtitle("1980 Census, }957\mathrm{ US cities")
```

Cumulative of median family income
1980 Census, 957 US cities

It would have been enough to type line cum faminc, but we wanted to make the graph look better; see [G-2] graph twoway line.

If we had wanted a weighted cumulative, we would have typed cumul faminc [w=pop] at the first step.

## > Example 2

To graph two (or more) cumulatives on the same graph, use cumul and stack; see [D] stack. For instance, we have data on the average January and July temperatures of 956 US cities:

```
. use https://www.stata-press.com/data/r18/citytemp, clear
(City temperature data)
. cumul tempjan, gen(cjan)
. cumul tempjuly, gen(cjuly)
. stack cjan tempjan cjuly tempjuly, into(c temp) wide clear
. line cjan cjuly temp, sort ytitle("") xtitle("Temperature (F)")
> title("Cumulatives:" "Average January and July temperatures")
> subtitle("956 US cities") legend(label(1 January) label(2 July))
```

Cumulatives:
Average January and July temperatures
956 US cities

As before, it would have been enough to type line cjan cjuly temp, sort. See [D] stack for an explanation of how the stack command works.

## - Technical note

According to Beniger and Robyn (1978), Fourier (1821) published the first graph of a cumulative frequency distribution, which was later given the name "ogive" by Galton (1875).

Jean Baptiste Joseph Fourier (1768-1830) was born in Auxerre in France. As a young man, Fourier became entangled in the complications of the French Revolution. As a result, he was arrested and put into prison, where he feared he might meet his end at the guillotine. When he was not in prison, he was studying, researching, and teaching mathematics. Later, he served Napolean's army in Egypt as a scientific adviser. Upon his return to France in 1801, he was appointed Prefect of the Department of Isère. While prefect, Fourier worked on the mathematical basis of the theory of heat, which is based on what are now called Fourier series. This work was published in 1822, despite the skepticism of Lagrange, Laplace, Legendre, and others-who found the work lacking in generality and even rigor-and disagreements of both priority and substance with Biot and Poisson.

## Acknowledgment

The equal option was added by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the Stata Journal and author of Speaking Stata Graphics.

## Title

cusum - Cusum plots and tests for binary variables

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Acknowledgment |
| Reference | Also see |  |  |

## Description

cusum graphs the cumulative sum (cusum) of a binary (0/1) variable, yvar, against a (usually) continuous variable, xvar.

## Quick start

Cusum statistics for binary variable y and graph of cumulative sum against values of x cusum y x

Also generate cs to store the cumulative sum

```
cusum y x, generate(cs)
```

Set the seed first for reproducible results
set seed 87534690
cusum $y$ x, generate(cs)
Cumulative sum of y against a variable containing fitted values yhat
cusum y x, yfit(yhat)

## Menu

Statistics $>$ Other $>$ Quality control $>$ Cusum plots and tests for binary variables

## Syntax

```
cusum yvar xvar [if] [in] [, options]
```

options
Description
Main
generate (newvar) save cumulative sum in newvar
yfit (fitvar) calculate cumulative sum against fitvar
nograph suppress the plot
nocalc
suppress cusum test statistics
Cusum plot
connect_options
affect the rendition of the plotted line
Add plots
addplot (plot) add plots to the generated graph
Y axis, X axis, Titles, Legend, Overall
twoway_options any options other than by() documented in [G-3] twoway_options
collect is allowed; see [U] 11.1.10 Prefix commands.

## Options

## Main

generate (newvar) saves the cusum in newvar.
yfit (fitvar) calculates a cusum against fitvar, that is, the running sums of the "residuals" fitvar minus yvar. Typically, fitvar is the predicted probability of a positive outcome obtained from a logistic regression analysis.
nograph suppresses the plot.
nocalc suppresses calculation of the cusum test statistics.
$\qquad$ Cusum plot
connect_options affect the rendition of the plotted line; see [G-3] connect_options.

```
            Add plots
    addplot (plot) provides a way to add other plots to the generated graph. See [G-3] addplot_option.
```

$\qquad$ Y axis, X axis, Titles, Legend, Overall
twoway_options are any of the options documented in [G-3] twoway_options, excluding by (). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

## Remarks and examples

The cusum is the running sum of the proportion of ones in the sample, a constant number, minus yvar,

$$
c_{j}=\sum_{k=1}^{j} f-y \operatorname{var}_{(k)}, \quad 1 \leq j \leq N
$$

where $f=\left(\sum y v a r\right) / N$ and $y v a r_{(k)}$ refers to the corresponding value of $y v a r$ when $x v a r$ is placed in ascending order: $\operatorname{xvar}_{(k+1)} \geq \operatorname{xvar}_{(k)}$. Tied values of xvar are broken at random. If you want them broken the same way in two runs, you must set the random-number seed to the same value before giving the cusum command; see [R] set seed.

A U-shaped or inverted U-shaped cusum indicates, respectively, a negative or a positive trend of $y v a r$ with xvar. A sinusoidal shape is evidence of a nonmonotonic (for example, quadratic) trend. cusum displays the maximum absolute cusum for monotonic and nonmonotonic trends of yvar on xvar. These are nonparametric tests of departure from randomness of yvar with respect to xvar. Approximate values for the tests are given.

## > Example 1

For the automobile dataset, auto.dta, we wish to investigate the relationship between foreign ( $0=$ domestic, $1=$ foreign) and car weight as follows:
. use https://www.stata-press.com/data/r18/auto

| (1978 automobile data) |  |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| . cusum foreign weight |  |  |  |  |  |  |  |  |
| Variable | Obs | $\operatorname{Pr}(1)$ | CusumL | zL | Pr>zL | CusumQ | zQ | Pr>zQ |
| foreign | 74 | 0.2973 | 10.30 | 3.963 | 0.000 | 2.92 | 0.064 | 0.475 |

The resulting plot, which is U-shaped, suggests a negative monotonic relationship. The trend is confirmed by a highly significant linear cusum statistic, labeled CusumL in the output above.

Some $29.73 \%$ of the cars are foreign (coded 1). The proportion of foreign cars diminishes with increasing weight. The domestic cars are crudely heavier than the foreign ones. We could have discovered that by typing table foreign, statistics(mean weight), but such an approach does not give the full picture of the relationship. The quadratic cusum (CusumQ) is not significant, so we do not suspect any tendency for the very heavy cars to be foreign rather than domestic. A slightly
enhanced version of the plot shows the preponderance of domestic (coded 0) cars at the heavy end of the weight axis:

| Clabel values foreign |
| :--- |
| . cusum foreign weight, |
| V (none) |
| Variable |
|  |
| foreign |

The example is, of course, artificial, because we would not really try to model the probability of a car being foreign given its weight.

## Stored results

cusum stores the following in $r()$ :
Scalars

| $r(N)$ | number of observations | $r\left(P \_z l\right)$ | $p$-value for test (linear) |
| :--- | :--- | :--- | :--- |
| $r(p r o p 1)$ | proportion of positive outcomes | $r(c u s u m q)$ | quadratic cusum |
| $r($ cusuml $)$ | cusum | $r(z q)$ | test (quadratic) |
| $r(z l)$ | test (linear) | $r\left(P_{-z q)}\right.$ | $p$-value for test (quadratic) |

## Acknowledgment

cusum was written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model.

## Reference

Royston, P. 1992. The use of cusums and other techniques in modelling continuous covariates in logistic regression. Statistics in Medicine 11: 1115-1129. https://doi.org/10.1002/sim. 4780110813.

## Title

db — Launch dialog

> Description Syntax Options Remarks and examples Also see

## Description

db opens the dialog box for the specified command. Programmers who wish to allow the launching of dialogs from a help file, see [P] smcl for information on the dialog SMCL directive.
set maxdb sets the maximum number of dialog boxes whose contents are remembered from one invocation to the next during a session. The default value of maxdb is 50 .

## Syntax

Syntax for $d b$
db commandname

For programmers
db commandname [, message(string) debug dryrun]
Set system parameter

```
set maxdb # [, permanently]
```

where \# must be between 5 and 1,000 .

## Options

message (string) specifies that string be passed to the dialog box, where it can be referred to from the __MESSAGE STRING property.
debug specifies that the underlying dialog box be loaded with debug messaging turned on.
dryrun specifies that, rather than launching the dialog, db show the commands it would issue to launch the dialog.
permanently specifies that, in addition to making the change right now, the maxdb setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

The usual way to launch a dialog is to open the Data, Graphics, or Statistics menu and to make your selection from there. When you know the name of the command that you want to run, however, db provides a way to invoke the dialog from the command line.
db follows the same abbreviation rules that Stata's command-line interface follows. So, to launch the dialog for regress, you can type

[^18]or
. db reg
Say that you use the dialog box for regress, either by selecting

## Statistics > Linear models and related > Linear regression

or by typing
. db regress
You fit a regression.
Much later during the session, you return to the regress dialog box. It will have the contents as you left them if 1) you have not typed clear all between the first and second invocations; 2) you have not typed discard between the two invocations; and 3) you have not used more than 50 different dialog boxes-regardless of how many times you have used each-between the first and second invocations of regress. If you use 51 or more, the contents of the regress dialog box will be forgotten.
set maxdb determines how many different dialog boxes are remembered. A dialog box takes, on average, about 20 KB of memory, so the 50 default corresponds to allowing dialog boxes to consume about 1 MB of memory.

## Also see

[R] query - Display system parameters

## Title

demandsys - Estimation of flexible demand systems

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| Acknowledgment | References | Also see |  |

## Description

demandsys fits demand systems, sets of equations derived from economic theory that describe consumers' purchases of various goods or services. demandsys allows you to fit eight different demand systems, including the Cobb-Douglas system, the almost ideal demand system (AIDS) of Deaton and Muellbauer (1980b), the translog indirect utility demand system of Christensen, Jorgenson, and Lau (1975), and variants of the latter two. You can also include demographic variables that affect a consumer's or household's demands.

## Quick start

Fit an AIDS demand system with four goods with expenditure shares w1, w2, w3, and w4; prices, p1, $\mathrm{p} 2, \mathrm{p} 3$, and p 4 ; and total expenditure, totexp

```
demandsys aids w1 w2 w3 w4, prices(p1 p2 p3 p4) ///
expenditure(totexp)
```

Same as above, reporting Marshallian (uncompensated) elasticities rather than coefficients

```
demandsys aids w1 w2 w3 w4, prices(p1 p2 p3 p4) ///
expenditure(totexp) elasticities(uncompensated) ///
nocoeftable
```

Same as above, labeling goods in output for easier interpretation

```
demandsys aids w1 w2 w3 w4, prices(p1 p2 p3 p4) ///
expenditure(totexp) elasticities(uncompensated) ///
nocoeftable labels("apples bananas carrots dates")
```

Fit a quadratic AIDS model with four goods, controlling for x 1 and x 2 using demographic translation

```
demandsys quaids w1 w2 w3 w4, prices(p1 p2 p3 p4)
                                    ///
        expenditure(totexp) demographics(x1 x2)
```

Same as above, but use demographic scaling rather than translating

```
demandsys quaids w1 w2 w3 w4, prices(p1 p2 p3 p4)///expenditure(totexp) demographics(x1 \(x 2\), scaling)
```

## Menu

Statistics $>$ Linear models and related $>$ Multiple-equation models $>$ Demand system

## Syntax

varlist $t_{s}$ indicates the list of $G$ variables containing the expenditure shares of the $G$ goods in the model.
options
Description

## Main

*prices (varlist ${ }_{p}$ )

* expenditure (varname)
demographics(varlist ${ }_{d}[$, scaling])
specify the variables containing prices
specify the variable containing total expenditure
specify other variables affecting a consumer's demand for the goods; use demographic scaling instead of translating
piconstant(\#)
specify constant term in transcendental logarithmic price index

SE/Robust
vce (vcetype)
vcetype may be gnr, robust, cluster clustvar, bootstrap, or jackknife

Reporting elasticities (e_type)
labels (string)
level(\#)
noheader
nocoeftable
display_options
Optimization
optimization_options
coeflegend
report elasticities; e_type may be expenditure, compensated, or uncompensated
specify labels for goods
set confidence level; default is level (95)
suppress the summary header at the top of the output
do not display the table of estimated coefficients control columns and column formats and line width
control the optimization process; seldom used
display legend instead of statistics
*prices() and expenditure() are required.
collect is allowed; see [U] 11.1.10 Prefix commands.
aweights, fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

Main
prices (varlist ${ }_{p}$ ) specifies a list of $G$ variables corresponding to the prices of the $G$ goods faced by each consumer. The number of variables specified here must match the number specified in varlist , and the price variables must be specified in the same order as the share variables. All the price variables must be strictly positive for all the demand systems implemented. prices() is required.
expenditure (varname) specifies the variable corresponding to the total expenditure on all goods within the system by each consumer. This variable must be strictly positive. expenditure() is required.
demographics (varlist ${ }_{d}[$, scaling]) specifies one or more demographic variables that affect each consumer's demand for the goods in the system. Suboption scaling, available only with models aids and quaids, requests that demographics be incorporated via demographic scaling rather than demographic translation, the default.
piconstant(\#) specifies the value of the constant term in the transcendental logarithmic price index; by default, this is set to the logarithm of the minimum expenditure observed in the sample. This option is relevant only for models aids and quaids.

## SE/Robust

vce (vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (gnr), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
vce (gnr), the default, uses the conventionally derived variance estimator for nonlinear models fit using Gauss-Newton regression.

Reporting
elasticities (e_type) requests that elasticities be reported instead of, or in addition to, the parameter estimates. e_type may be expenditure, compensated, or uncompensated. expenditure computes demand elasticity to changes in expenditure. compensated computes demand elasticity to changes in prices, ignoring income effects. These elasticities are also known as Hicksian price elasticities. uncompensated computes demand elasticity to changes in prices. These elasticities are also known as Marshallian price elasticities. The elasticities are computed at the estimation sample means of the prices, expenditures, and any demographic variables specified. For more flexibility in obtaining elasticities, use the postestimation command estat elasticities.
labels(string) specifies a set of names with which the goods are to be labeled. By default, if you specify a four-good demand system, then the goods will be labeled generically: "Good 1", "Good 2", "Good 3", and "Good 4".

If you specify labels("shelter fuel food other"), then the four goods will be labeled "shelter", "fuel", "food", and "other" in the output. If you specify a demand system with $G$ goods, then you must supply $G$ labels separated by spaces.

## level(\#); see [R] Estimation options.

noheader requests that the header summarizing the model, estimation sample, and other statistics not be shown in the output.
nocoeftable requests that the table containing the parameter estimates, their standard errors, and so on not be displayed. Typically, you would use this option if you specify the elasticities() option.
display_options: noci, nopvalues, cformat (\%fmt), pformat (\%fmt), sformat (\%fmt), and nolstretch; see [R] Estimation options.

Optimization
optimization_options: iterate (\#), [no]log, trace, eps (\#), ifgnlsiterate(\#), ifgnlseps(\#), and delta(\#).
iterate(\#) specifies the maximum number of iterations to use for nonlinear least squares at each round of feasible generalized nonlinear least-squares (FGNLS) estimation. The default is the number set using set maxiter, which is 300 by default.
$\log$ and nolog specify whether to display the iteration $\log$. The iteration $\log$ is displayed by default unless you used set iterlog off to suppress it; see set iterlog in [R] set iter.
trace specifies that the iteration $\log$ should include the current parameter vector.
eps (\#) specifies the convergence criterion for successive parameter estimates and for the residual sum of squares. The default is eps (1e-5) (0.00001). eps () also specifies the convergence criterion for successive parameter estimates between rounds of iterative FGNLS.
ifgnlsiterate(\#) specifies the maximum number of FGNLS iterations to perform. The default is the number set using set maxiter, which is 300 by default.
ifgnlseps (\#) specifies the convergence criterion for successive estimates of the error covariance matrix during iterative FGNLS estimation. The default is ifgnlseps (1e-10).
delta(\#) specifies the relative change in a parameter, $\delta$, to be used in computing the numeric derivatives. The derivative for parameter beta $a_{i}$ is computed as

$$
\left\{f_{i}\left(\mathbf{x}_{i}, \beta_{1}, \beta_{2}, \ldots, \beta_{i}+d, \beta_{i+1}, \ldots\right)-f_{i}\left(\mathbf{x}_{i}, \beta_{1}, \beta_{2}, \ldots, \beta_{i}, \beta_{i+1}, \ldots\right)\right\} / d
$$

where $d=\delta\left(\left|\beta_{i}\right|+\delta\right)$. The default is delta(4e-7).
The following option is available with demandsys but is not shown in the dialog box:
coeflegend; see [R] Estimation options.

QUAIDS
Controlling for demographic factors
Demographic translation
Demographic scaling
Epilogue

## Introduction

demandsys fits demand systems, sets of equations derived from economic theory that describe consumers' purchases of various goods or services. Typically, you will have a large cross-sectional survey containing consumers' data on their expenditures on various goods and services along with the prices paid for them. We often refer to the items as "goods" for brevity, but of course some of the items may be services. Whether they are physical goods or intangible services, in the context of utility-maximizing consumers, they are both goods in the sense that "more is better". We also use the term "purchase" somewhat loosely; in some cases, what we are interested in is not the actual purchase of goods but rather their consumption over a fixed time period.

To fit a demand system, you must first decide on what is in the consumption basket or bundle and the set of goods whose demands you wish to model. Using the parameters from the model, you may then obtain the elasticities-the effects of changes in prices or changes in expenditure on demand of goods. You may also perform welfare analysis by contrasting changes in demand or utility that occur at different price or expenditure levels. We assume that you have decided which consumption bundle to model already or else that you have several alternative baskets to model and compare.

The left-hand-side variables you specify with demandsys are expenditure shares, the shares of total expenditure spent on goods or services. Given $p_{g}$ (the price of good $g$ ), $q_{g}$ (the quantity of good $g$ purchased), and $m$ (the consumer's total expenditure on all goods within the demand system), the expenditure share for good $g$ is defined as

$$
w_{g}=\frac{p_{g} q_{g}}{m}
$$

demandsys requires that you have the prices of all the goods and that you have the total expenditure across all the goods. demandsys does not need the quantities of the goods purchased, though you may need them to calculate the expenditure shares.

Consumer theory in microeconomics presents demand models in terms of quantities. In demand system analysis, we model expenditure shares, not quantities. By our definition of total expenditure, $0 \leq w_{g} \leq 1$ for all $g$, and $\sum_{g} w_{g}=1$. For all but the simplest utility or cost functions, the algebra to obtain expenditure shares is arguably easier than that to obtain quantities. demandsys checks your expenditure shares for all goods and will exit with an error message if an expenditure share is found outside that range or if the sum is not equal to one (allowing for small rounding errors).

You may also specify additional variables that may affect a consumer's purchase decisions. These are often demographic variables, such as the number of children and adults in a household, or a set of indicator variables to denote the region of a country in which a consumer is located. If you have data that were collected over the course of different months or years, you may wish to include indicators to control for the time at which the consumer's purchases were observed. We call all of these variables demographics, even if some of these variables are not really demographic characteristics.

Based on the theoretical considerations in Lewbel (2001), we strongly encourage you to include demographic variables in your model. He shows that econometrically estimated demand functions will not satisfy rationality conditions unless other variables that affect demand and are correlated with expenditures are included. Conversely, if we include all such variables in our model, then the estimated demands will satisfy rationality even if preferences vary among households. On the other hand, you should also bear in mind that including too many demographic variables can greatly increase the number of parameters in your model, especially if your demand system includes many goods.
demandsys offers just a small sampling of demand systems that have been proposed in the literature. As a practical matter, which one should you use? We have included the Cobb-Douglas model mainly for pedagogical purposes because most students are familiar with Cobb-Douglas utility, though soon thereafter they learn about its severe restrictions on consumer behavior. Stone's (1954) linear expenditure system (LES) is historically important as an early demand system but also places somewhat strong restrictions on consumer behavior. Christensen, Jorgenson, and Lau's (1975) translog model relaxes some of the LES's restrictions. It is not as widely used as some of the newer models, though a very similar translog production function those authors proposed continues to see extensive use. Shortly after the translog model arrived, Deaton and Muellbauer (1980b) proposed their more flexible AIDS, which has been a workhorse model of demand system analysis ever since its arrival. Banks, Blundell, and Lewbel (1997) provided a quadratic extension to AIDS that is also popular.

Banks, Blundell, and Lewbel (1997) suggest using QUAIDS because of its flexibility. Moreover, QUAIDS satisfies certain theoretical properties developed in Gorman (1981); and it allows goods to be either luxuries or necessities depending on a consumer's income, which Banks, Blundell, and Lewbel (1997) show to be important in the data they consider.

With the AIDS and QUAIDS models, you can include demographics via two different methods: demographic translation and demographic scaling; see Demographic translation and Demographic scaling. If you believe that subsistence or committed quantities are appropriate for the goods you are modeling, you can use what we call the generalized QUAIDS model. If you do that, you should check to see that the subsistence quantity interpretation holds; we do that in example 2 of $[R]$ demandsys postestimation. You can also do a simple likelihood-ratio test to see whether the quadratic terms of these QUAIDS models increase their explanatory power over Deaton and Muellbauer's AIDS and its generalized variant; see example 5 below.

Throughout the rest of the discussion, we assume that you are familiar with a few basic microeconomic concepts, including utility maximization, the expenditure function, and the indirect utility function. The presentations in standard texts like Varian (1992, chap. 7-10) and Mas-Colell, Whinston, and Green (1995, chap. 3) provide good introductions to these concepts. The classic monograph by Deaton and Muellbauer (1980a) and the book by Pollak and Wales (1992) describe demand system analysis in much greater detail than space permits us here. More recent survey papers include Holt and Goodwin (2009) and Barnett and Serletis (2008). Fisher, Fleissig, and Serletis (2001) compare many flexible functional forms for demand system analysis, including several that are implemented by demandsys.

## Some notation

It will be useful to establish at the outset some standard notation we will use throughout this discussion. We use subscript $i=1, \ldots, N$ to index observations, $g=1, \ldots, G$ to index goods, and $d=1, \ldots, D$ to index demographic variables. In formulas where we must use double summations across goods or else have used subscript $g$ elsewhere, we also use $h=1, \ldots, G$ and $j=1, \ldots, G$ to index goods. When no confusion could arise, we omit the observation subscript to reduce the number of subscripts.

Let $w_{g}$ be the expenditure share for good $g$ defined as $w_{g} \equiv\left(p_{g} q_{g}\right) / m$, where $p_{g}$ is the price of good $g, q_{g}$ is the quantity of good $g$ consumed, and $m$ denotes total expenditure on all the goods in the system being modeled. We use the notation $\mathbf{p}$ to refer to the $G$-length vector of all $G$ prices. When we refer to $w_{g}$, we are referring to the observed expenditure share for good $g$ for consumer $i$. When we refer to, say, $w_{g}(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\beta})$, we are referring to an expenditure-share equation or function for good $g$ that depends on the prices of all the goods and total expenditure as well as parameter vectors $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$. We include the parameter vectors and matrices in the arguments for expenditure shares as well as some other functions to emphasize that they are estimated and will appear in the output from demandsys and that statistics available via predict or estat elasticities after estimation depend on those parameters.

The observed $w_{g}$ is assumed to be related to the expenditure-share function $w_{g}(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\beta})$ as

$$
w_{g}=w_{g}(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\beta})+\epsilon_{g}
$$

where $\epsilon_{g}$ is a zero-mean error term that we discuss in more detail in Methods and formulas.

## Cobb-Douglas

Although widely used in many economic models, the Cobb-Douglas utility function is arguably too simple for serious demand system analysis because of its severe restrictions on the expenditure-share equations and elasticities. For instance, it restricts expenditure elasticities to be identically equal to 1 for all goods. Nevertheless, we include it because it serves as a good starting point for our discussion and allows us to present various aspects of demandsys. For three goods, consumers maximize their Cobb-Douglas utility function subject to the constraint that total expenditure does not exceed the allocated budget,

$$
\begin{aligned}
& \max _{q_{1}, q_{2}, q_{3}} q_{1}^{\alpha_{1}} q_{2}^{\alpha_{2}} q_{3}^{\left(1-\alpha_{1}-\alpha_{2}\right)} \\
& \quad \text { subject to } p_{1} q_{1}+p_{2} q_{2}+p_{3} q_{3} \leq m
\end{aligned}
$$

where, without loss of generality, we have made the sum of the exponents of the Cobb-Douglas utility function sum to 1 . It is easy to show that the optimal quantities $q_{1}^{*}, q_{2}^{*}$, and $q_{3}^{*}$ are

$$
q_{1}^{*}=\alpha_{1} \frac{m}{p_{1}} \quad q_{2}^{*}=\alpha_{2} \frac{m}{p_{2}} \quad q_{3}^{*}=\left(1-\alpha_{1}-\alpha_{2}\right) \frac{m}{p_{3}}
$$

To obtain the expenditure-share function of, say, good 1 , we have

$$
w_{1}(\mathbf{p}, m ; \boldsymbol{\alpha})=\frac{p_{1} q_{1}}{m}=\alpha_{1} \frac{m}{p_{1}} \frac{p_{1}}{m}=\alpha_{1}
$$

and likewise for goods 2 and 3. Notice that the expenditure-share function for good $g$ is simply its coefficient $\alpha_{g}$ in the Cobb-Douglas utility function, or, equivalently, the coefficients in the CobbDouglas utility function are simply the shares of total expenditure allocated to each good. Most importantly, the expenditure shares for the Cobb-Douglas model are not functions of prices, income, or any other variables.

We made the sum of the exponents in the Cobb-Douglas utility function sum to 1 , and it is clear that $w_{1}+w_{2}+w_{3}=1$. Without the constraint on the sum, we would have to carry around the divisor $\alpha_{1}+\alpha_{2}+\alpha_{3}$ in our expenditure-share equations, but we would gain absolutely no additional insight. Moreover, with the constraint we need estimate only two parameters rather than three.

More generally, for a Cobb-Douglas utility function of the form

$$
u(\mathbf{q} ; \boldsymbol{\alpha})=\prod_{g=1}^{G} q_{g}^{\alpha_{g}} \quad \text { with } \quad \sum_{g=1}^{G} \alpha_{g}=1
$$

the expenditure-share function for the $g$ th good is simply $w_{g}(\mathbf{p}, m ; \boldsymbol{\alpha})=\alpha_{g}$.

## $>$ Example 1

We first describe the dataset we will use in this example and all others in this manual entry:
. use https://www.stata-press.com/data/r18/food_consumption
(Food consumption)

| . describe |  |  |
| :--- | :--- | :--- |
| Contains data from https://www.stata-press.com/data/r18/food_consumption.dta |  |  |
| Observations: | 4,160 | Food consumption |
| Variables: | 13 | 17 Jul 2022 16:03 |
|  |  | (_dta has notes) |

| Variable name | Storage type | Display format | Value <br> label | Variable label |
| :---: | :---: | :---: | :---: | :---: |
| w_dairy | float | \%10.6f |  | Expenditure share on dairy |
| w_proteins | float | \%10.6f |  | Expenditure share on meats and proteins |
| w_fruitveg | float | \%10.6f |  | Expenditure share on fruits and vegetables |
| w_flours | float | \%10.6f |  | Expenditure share on flours, breads, pasta, and cereals |
| w_misc | float | $\% 10.6 \mathrm{f}$ |  | Expenditure share on misc. food items |
| p_dairy | float | \%10.6f |  | Price of dairy |
| p_proteins | float | \%10.6f |  | Price of meats and proteins |
| p_fruitveg | float | \%10.6f |  | Price of fruits and vegetables |
| p_flours | float | \%10.6f |  | Price of flours, breads, pasta, and cereals |
| p_misc | float | \%10.6f |  | Price of misc. food items |
| expfd | float | \%10.6f |  | Total expenditure on all food categories |
| n_adults | byte | \%8.0g |  | \# adults in household |
| n_kids | byte | \%8.0g |  | \# kids in household |

Sorted by:
The observation level of this dataset is the household, and we have data on 4,160 households. The data include five categories of food: dairy products; proteins, including meats and fish; fruits and vegetables; flour-based products, including breads, pastas, and cereals; and a catchall category. For each of the five categories, we have the expenditure shares and prices, and we have the household's total expenditure on all five categories in the week that the household was surveyed. We also have demographic data for the household, including the numbers of children and adults.

Although we constructed the expenditure shares ourselves and know they sum to one, it is a good idea to verify that you have created your expenditure-share variables properly:
. egen wsum = rowtotal(w_dairy w_proteins w_fruitveg w_flours w_misc)
. summarize wsum

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| wsum | 4,160 | 1 | $4.40 \mathrm{e}-08$ | .9999999 | 1 |

demandsys will check that for you and exit with an error message if it is not the case, but doing so during your data management tasks may make debugging easier. demandsys will also check that all your price variables and expenditure variable are strictly positive, though again you might want to check those facts earlier in your data pipeline.

With a dataset in hand, we are ready to fit our first Cobb-Douglas demand system.

```
. demandsys cdouglas w_dairy w_proteins w_fruitveg w_flours w_misc,
> prices(p_dairy p_proteins p_fruitveg p_flours p_misc) expenditure(expfd)
Calculating NLS estimates:
Iteration 0: Residual SS = 180.2506
Iteration 1: Residual SS = 180.2506
Calculating FGNLS estimates:

[^19]We specified the command name, demandsys, followed by the model we wish to fit, cdouglas. We then specified the five expenditure-share variables, w_dairy through w_misc. The price variables, p_dairy through p_misc, go into the prices() option, and the expenditure variable, expfd, goes into the expenditure() option. demandsys uses a nonlinear multiple-equation estimator, so the top of the output includes an iteration log showing the model's convergence. In fact, the Cobb-Douglas model is linear, but that is the only model fit by demandsys that is. Stata uses the same nonlinear estimator for cdouglas as we use for the other demand systems. The header of the output includes $R^{2}$ values to get some idea of how well the model fits the data.

The table of coefficients is a bit different from most other estimators in Stata, which report coefficients organized by equations. The Cobb-Douglas model is unique in that each equation has its own parameter. However, that is not the case for any other demand system that demandsys fits. For most demand systems, many of the parameters appear in multiple equations, and there is no way to link parameters and equations. Hence, we cannot provide a coefficient table organized by equations as other multiple-equation estimators such as sureg provide. Instead, demandsys organizes estimates by parameter type.

We mentioned having a five-good demand system, so why do we see only four estimated parameters in the main output table? Recall that we used the normalization that the sum of the parameters in the Cobb-Douglas utility function is one. The upshot is that we really have only four free parameters because the fifth parameter must equal one minus the sum of the other four parameters. We provide the estimate of the fifth parameter in a separate table. It is computed separately using the parameter estimates of our fitted demand system and their standard errors. Given how the fifth parameter was computed, it does not share a covariance matrix with the other parameters and cannot be used for testing. We provide it here for reference.
demandsys shows only unconstrained parameters in the main estimation output because, with many goods and more complicated models, the output becomes long. Moreover, the estimated parameters themselves are of less interest than elasticities and other statistics derived from the fitted model.

## - Technical note

In the header of the output in the previous example, we see that the equation-level $R^{2}$ values are labeled as uncentered. Recall that the standard $R^{2}$ in regression analysis measures the ability of the model to predict the regressand compared with a model that contains just a constant term. For the Cobb-Douglas demand system, the expenditure shares are simply constant terms to be estimated. Hence, the traditional $R^{2}$ is by definition zero. We therefore report the uncentered $R^{2}$, which is an alternative that measures the model's explanatory power as a fraction of the sum of squares of an equation's left-hand-side variable. A higher uncentered $R^{2}$ is presumably better than a lower uncentered $R^{2}$, but you cannot compare the uncentered $R^{2}$ of a Cobb-Douglas share equation with the centered $R^{2}$ of a share equation from a different demand system.

The command estat elasticities, which is available after demandsys, allows you to calculate expenditure and price elasticities after fitting your demand system, and estat elasticities provides options to specify how those elasticities are calculated and for which observations. The full syntax for that command is listed in $[R]$ demandsys postestimation, but the basic command is easy to pick up as we work through examples below.

Here we use estat elasticities to obtain the expenditure elasticities for the estimation sample.

```
. estat elasticities, expenditure
Expenditure elasticities Number of obs = 4,160
```

| Expenditure | Elasticity |
| ---: | :---: |
| Good |  |
| 1 | 1 |
| 2 | 1 |
| 3 | 1 |
| 4 | 1 |
| 5 | 1 |

Note: No standard errors are displayed because all elasticities are identically equal to one.

The expenditure elasticities for all five goods are identically equal to one, and so the standard errors, test statistics, and confidence interval are not displayed because there is no sampling variance. The Cobb-Douglas function is an example of a utility function with "homothetic preferences", meaning that the ratio of two goods demanded by a consumer with such preferences depends only on the goods' relative prices and not on income. Homothetic preferences also imply that, regardless of changes in income, the shares consumed of each good remain the same; the expansion path of consumption is linear in income. The Cobb-Douglas case is a particularly extreme example, where the expenditure elasticities are one, the uncompensated own-price elasticities are minus one, and uncompensated cross-price elasticities are zero, which you can verify by typing

```
estat elasticities, uncompensated
```

Particularly with more complex demand systems, the coefficients themselves can be more difficult to interpret. Therefore, demandsys allows you to request that expenditure, uncompensated price, or compensated price elasticities be displayed in addition to, or in place of, the table of estimated coefficients. The elasticities reported directly by demandsys are calculated at the estimation sample means of prices, expenditures, and any demographics that you specify. To obtain, say, the uncompensated price elasticities instead of the coefficient table from a Cobb-Douglas demand system, you would type

```
demandsys cdouglas ..., prices(...) expenditure(...) ///
    elasticities(uncompensated) nocoeftable
```

estat elasticities gives you much more flexibility in terms of the sample used, and you can even specify particular prices or expenditures at which you want the elasticities to be calculated.

## Linear expenditure system (LES)

Nobel laureate Sir Richard Stone's estimation of the LES, developed based on theory by Nobel laureates Paul Samuelson and Lawrence Klein, together with Herman Rubin, represents the genesis of flexible demand system estimation (Stone 1954). LES provides for more flexible consumption patterns than the Cobb-Douglas model. The LES begins with the utility function

$$
u(\mathbf{q} ; \boldsymbol{\beta}, \boldsymbol{\mu})=\prod_{g}\left(q_{g}-\mu_{g}\right)^{\beta_{g}}
$$

where $\mu_{g}$ is the $g$ th element of $G \times 1$ vector $\mu$, which is to be estimated. This utility function results from translating or shifting the origin of the Cobb-Douglas utility function; utility does not accrue from good $g$ unless its consumption exceeds an amount $\mu_{g}$. That parameter is known as a subsistence or committed quantity that a consumer must purchase for survival. $\beta_{g}$ is the $g$ th element of $G \times 1$ vector $\boldsymbol{\beta} . \beta_{g}$ measures the share of supernumerary expenditure, namely, the share of remaining expenditure once all subsistence quantities have been purchased, on good $g$. As in the Cobb-Douglas case, we normalize the $G \times 1$ parameter vector $\boldsymbol{\beta}$ so that $\sum_{g} \beta_{g}=1$. Thus, the model has $2 G-1$ parameters we must estimate.

Solving

$$
\max _{\mathbf{q}} \prod_{g}\left(q_{g}-\mu_{g}\right)^{\beta_{g}} \quad \text { s. t. } \quad \mathbf{p}^{\prime} \mathbf{q} \leq m
$$

yields the expenditure-share functions

$$
w_{g}(\mathbf{p}, m ; \boldsymbol{\beta}, \boldsymbol{\mu})=\frac{p_{g} \mu_{g}}{m}+\beta_{g}\left(1-\sum_{h} \frac{p_{h} \mu_{h}}{m}\right)
$$

The term to the left of the plus sign is the fraction of expenditure that must be spent on good $g$ to maintain subsistence. To the right, the term bound in parentheses is the fraction of expenditure left after the subsistence level for all other goods has been spent. Of this amount, a share $\beta_{g}$ is spent on good $g$. The normalization that $\sum_{g} \beta_{g}=1$ ensures that $\sum_{g} w_{g}(\mathbf{p}, m)=1$, as must be true of a demand system.

While we have interpreted the $\mu_{g}$ as minimum required amounts of each good, there is no requirement that $\mu_{g}>0$ for all $g$, nor do we impose any such constraints during estimation. Moreover, for this interpretation to hold we must have that for each household $i, \sum_{g} p_{g i} \mu_{g i} \leq m_{i}$.

## > Example 2

Here we fit an LES to the same data as in example 1.

```
Note: beta estimates sum to 1.
Shares: w_dairy w_proteins w_fruitveg w_flours w_misc
Prices: p_dairy p_proteins p_fruitveg p_flours p_misc
Expenditure: expfd
```

We specified the nolog option to suppress the detailed iteration log. We first noticed that the $R^{2}$ for the model for Good 1 is actually negative. Because the equations here are nonlinear, the value of $R^{2}$ is not constrained to be between 0 and 1 ; that is only true for linear regression. The footer of the table with normalized parameters reemphasizes the fact that we have made $\sum_{g} \beta_{g}=1$.

All the $\mu$ parameters are greater than zero. The $\mu$ parameter for Good 3, fruits and vegetables, is largest, implying the physical quantity of them required is much higher than the other four goods. However, we should also look at the average prices of the goods:

| . summarize p_* |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| Variable | Obs | Mean | Std. dev. | Min | Max |
| p_dairy | 4,160 | .4387958 | .4238236 | .1041262 | 18 |
| p_proteins | 4,160 | 1.729284 | .69554 | .3333333 | 9.258823 |
| p_fruitveg | 4,160 | .5472199 | .1945325 | .1073369 | 2.672269 |
| p_flours | 4,160 | 1.49421 | .6816424 | .0805687 | 7.202127 |
| p_misc | 4,160 | 1.47115 | .8588024 | .1428571 | 15.74629 |

Based on the average price of each good, the dollar amount of protein required for survival is only 9 cents less than the dollar amount of fruits and vegetables required $(2.368 \times 0.547=\$ 1.30$ versus $0.698 \times 1.729=\$ 1.21$ ).

As we mentioned in the introductory remarks, if you have demographic variables, you should incorporate them into your model. demandsys incorporates demographics into models by applying Pollak and Wales's (1978) "demographic translation" to the expenditure-share equations. Just as the linear expenditure system is a translated version of the Cobb-Douglas system, Pollak and Wales incorporate demographics by translating the consumer's available level of expenditures.

Suppose for each consumer we have a $D \times 1$ vector of demographic characteristics $\mathbf{d}$. We have $G$ expenditure-share equations, so associated with $\mathbf{d}$ is a $G \times D$ matrix of parameters $\mathbf{N}$ with typical row $\boldsymbol{\nu}_{g}$. Let $\mathbf{c}=\mathbf{N d}$ with typical element $c_{g}$. In demographic translation, we write each translated demand function as

$$
\bar{x}_{g}(\mathbf{p}, m, \mathbf{c})=c_{g}+x_{g}\left(\mathbf{p}, m-\sum_{h} p_{h} c_{h}\right)
$$

For the LES, we have

$$
\bar{x}_{g}(\mathbf{p}, m, \mathbf{d} ; \boldsymbol{\beta}, \boldsymbol{\mu}, \mathbf{N})=\left(\mu_{g}+c_{g}\right)+\frac{\beta_{g}}{p_{g}}\left(m-\sum_{h} p_{h} \mu_{h}-\sum_{h} p_{h} c_{h}\right)
$$

so that

$$
\bar{w}_{g}(\mathbf{p}, m, \mathbf{d} ; \boldsymbol{\beta}, \boldsymbol{\mu}, \mathbf{N})=\frac{p_{g}\left(\mu_{g}+\boldsymbol{\nu}_{g} \mathbf{d}\right)}{m}+\beta_{g}\left\{1-\frac{\sum_{h} p_{h}\left(\mu_{h}+\boldsymbol{\nu}_{h} \mathbf{d}\right)}{m}\right\}
$$

For the LES, the effect of the demographic variables is to adjust the $\mu$ parameters, though we must be cautious in interpreting the term $\mu_{g}+\nu_{g} \mathbf{d}$ as a minimum required quantity because there is nothing preventing it from being negative.

## > Example 3

The dataset described in example 1 also includes two demographic characteristics, the numbers of children and adults in each household. Here we refit the LES to these data, controlling for these two demographics.

```

Expenditure: expfd
Demographics: n_kids n_adults
The estimated parameter matrix $\mathbf{N}$ is shown in the last block of the coefficient table, and demandsys labels the coefficients using factor-variable notation. Yet you should not think of the terms as you would of interactions in a regression. Here the notation means something different. The first five rows of the output for $\mathbf{N}$ correspond to the demographic variable $n \_k i d s$ and how it affects the consumption of each good. The remaining five correspond to n_adults. For instance, all the coefficients for n_adults are positive, as we would expect, meaning that having more adults in the family increases consumption of all goods. The coefficient for $n \_k i d s$ on the consumption of Good 3, fruits and vegetables, is negative, meaning consumption decreases as the number of children increases.

Directly interpreting the coefficients on demographic variables is not difficult for the LES, but for more complicated models, it can be. One easy way to see the practical effect of that negative coefficient is to use the margins command to see how our predicted quantity for Good 3 changes as the number of children changes.

```
. margins, predict(quantities equation(#3)) at(n_kids=1 n_kids=2 n_kids=3)
Predictive margins Number of obs = 4,160
Model VCE: GNR
Expression: Predicted quantity of good 3, predict(quantities equation(#3))
1._at: n_kids = 1
2._at: n_kids = 2
3._at: n_kids = 3
```

|  | Delta-method <br> std. err. |  |  |  | z | $\mathrm{P}>\|\mathrm{z}\|$ |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Margin | [95\% conf. interval] |  |  |  |  |  |
| at |  |  |  |  |  |  |
| 2 | 22.57831 | .1734791 | 130.15 | 0.000 | 22.2383 | 22.91833 |
| 3 | 20.23569 | .323032 | 62.64 | 0.000 | 19.60256 | 20.86882 |

We asked margins to produce predictions of quantities of Good 3, fruits and vegetables, by specifying the equation(\#3) option, and we asked it to do so when the number of children is equal to one, again when the number of children is equal to two, and finally when the number of children is equal to three. margins first sets $n \_k i d s$ equal to one for all 4,160 observations in the estimation sample and obtains the predicted quantities; the mean of those predictions is 22.6 . When $\mathrm{n} \_\mathrm{kids}$ is equal to two for all observations, the mean is 21.4, and when $n \_k i d s$ is equal to three, the mean is 20.2 .

Kids do not always eat their fruits and vegetables, but finding that the quantity of fruits and vegetables actually declines as the household grows is rather surprising. Perhaps we have omitted
other relevant demographic variables from our model, biasing our estimates, or perhaps the model itself is simply too rigid.

Finally, we use estat elasticities to obtain uncompensated price elasticities. We will obtain two sets of results, one for households with fewer than three kids and one for households with three or more kids.

| 5 | -. 7542306 | . 0156676 | -48.14 | 0.000 | $-.7849385$ | -. 7235226 |

For example, in the table for households with 3 or more children, the price elasticity for Good 5 with respect to Good 1 is -0.0356486 . Among these households, if the price of Good 5 (miscellaneous items) increases by $1 \%$, then the quantity of Good 1 (dairy products) purchased will decrease by an average of $0.036 \%$.

We summarize the own-price elasticities in table 1. We again focus on the demand for fruits and vegetables. Among households with two children or fewer, it is inelastic, while it is (barely) elastic for households with three or more children. Again, we have no explanation for why that would be the case, though we suspect the model is simply too rigid to accurately model the consumption patterns seen in our data.

Table 1: Own-price elasticities based on number of children

|  | \# of Children |  |
| :--- | :---: | :---: |
| Good | $\leq 2$ | $\geq 3$ |
| Dairy | -0.954 | -0.940 |
| Proteins | -0.939 | -0.967 |
| Fruits \& vegetables | -0.887 | -1.001 |
| Flours | -0.711 | -0.684 |
| Miscellany | -0.782 | -0.754 |

## Translog

Pollak and Wales (1992, sec. 3.1) discuss an entire class of demand systems that they describe as the transcendental logarithmic or "translog" family. We implement the version they call the "basic translog" function, which is probably the most well known, because it corresponds to the translog indirect utility function proposed by Christensen, Jorgenson, and Lau (1975). We also implement the version Pollak and Wales call the "generalized translog" function, which is a more flexible version of the basic translog that has been translated in a way analogous to how the LES is a shifted version of the Cobb-Douglas utility function.

## Basic translog

Christensen, Jorgenson, and Lau (1975) proposed both direct and indirect utility functions with the "translog" functional form. For their direct utility function, they obtain expenditure shares that are a function of expenditure and quantities, which is not the focus of demandsys. We instead implement the demand system based on their translog indirect utility function. The starting point is the indirect utility function

$$
\begin{equation*}
\ln v(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\Gamma})=-\sum_{g} \alpha_{g} \ln \frac{p_{g}}{m}-\frac{1}{2} \sum_{g} \sum_{h} \gamma_{g h} \ln \frac{p_{g}}{m} \ln \frac{p_{h}}{m} \tag{1}
\end{equation*}
$$

Equation (1) is twice differentiable in prices, and based on Young's (1909) theorem, we must have $\gamma_{g h}=\gamma_{h g}$ for all $g$ and $h$. (Young's theorem states that cross-partial derivatives are equal.)

Roy (1943) introduced what would be known as Roy's identity, which equates a consumer's Marshallian demand function for a good with a function of their indirect utility function. Applying Roy's identity, we have the expenditure-share functions

$$
w_{g}(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\Gamma})=\frac{\alpha_{g}+\sum_{h} \gamma_{g h} \ln \frac{p_{h}}{m}}{1+\sum_{j} \sum_{h} \gamma_{j h} \ln \frac{p_{h}}{m}}
$$

where we have imposed the normalization $\sum_{g} \alpha_{g}=1$. This ensures that the expenditure shares sum to 1 , a property known as "additivity".

As we remarked in the introduction, if one has relevant demographic variables, one should include them in the demand system, so we will not present an example of the translog model without demographic variables. Moreover, it is in fact easier to describe how we incorporate demographic variables into the translog system if we first describe the generalized translog model.

## Generalized translog

Another way to perform translation and introduce subsistence or committed quantities into a demand system is to translate the indirect utility function, so that consumers' effective expenditures are their expenditures after the subsistence quantities of all goods are purchased. Pollak and Wales $(1992,56)$ do this to Christensen, Jorgenson, and Lau's (1975) indirect utility function to obtain

$$
\begin{aligned}
\ln v(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\Gamma}, \boldsymbol{\mu}) & =-\sum_{g} \alpha_{g} \ln \frac{p_{g}}{\bar{m}}-\frac{1}{2} \sum_{g} \sum_{h} \gamma_{g h} \ln \frac{p_{g}}{\bar{m}} \ln \frac{p_{h}}{\bar{m}} \\
\bar{m} & =m-\sum_{h} p_{h} \mu_{h} \quad \sum_{h} \alpha_{h}=1 \quad \gamma_{g h}=\gamma_{h g}
\end{aligned}
$$

where again $\boldsymbol{\mu}$ is a $G \times 1$ vector of subsistence quantities with typical element $\mu_{g}$. A tedious but straightforward application of Roy's identity gives the expenditure-share functions as

$$
\begin{aligned}
w_{g}(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\Gamma}, \boldsymbol{\mu}) & =\frac{p_{g} \mu_{g}}{m}+\frac{\bar{m}}{m}\left(\frac{\alpha_{g}+\sum_{h} \gamma_{g h} \ln \frac{p_{h}}{\bar{m}}}{1+\sum_{j} \sum_{h} \gamma_{j h} \ln \frac{p_{h}}{\bar{m}}}\right) \\
\bar{m} & =m-\sum_{h} p_{h} \mu_{h} \quad \sum_{h} \alpha_{h}=1 \quad \gamma_{h j}=\gamma_{j h}
\end{aligned}
$$

It is apparent that the sum of $w_{g}(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\Gamma}, \boldsymbol{\mu})$ across all $g$ is equal to one, as must be true of a demand system. Again, suppose for each consumer that we have a $D \times 1$ vector of demographics $\mathbf{d}$ and an associated $G \times D$ matrix $\mathbf{N}$, and again, let $c_{g}$ denote the $g$ th element of the vector $\mathbf{c}=\mathbf{N d}$.

To apply both demographic characteristics and committed quantities, we can translate the translog indirect utility function, this time with the value $\left(\mu_{g}+c_{g}\right)$ replacing $\mu_{g}$ in the developments above. Thus, the generalized translog system with demographic variables has expenditure-share functions of the form

$$
\begin{aligned}
w_{g}(\mathbf{p}, m, \mathbf{d} ; \boldsymbol{\alpha}, \boldsymbol{\Gamma}, \boldsymbol{\mu}, \mathbf{N}) & =\frac{p_{g}\left(\mu_{g}+\boldsymbol{\nu}_{g} \mathbf{d}\right)}{m}+\frac{\bar{m}}{m}\left(\frac{\alpha_{g}+\sum_{h} \gamma_{g h} \ln \frac{p_{h}}{\bar{m}}}{1+\sum_{j} \sum_{h} \gamma_{j h} \ln \frac{p_{h}}{\bar{m}}}\right) \\
\bar{m} & =m-\sum_{h} p_{h}\left(\mu_{h}+\boldsymbol{\nu}_{h} \mathbf{d}\right) \quad \sum_{h} \alpha_{h}=1 \quad \gamma_{h j}=\gamma_{j h}
\end{aligned}
$$

The basic translog model results if we set $\boldsymbol{\mu}=\mathbf{0}$ and $\mathbf{N}=\mathbf{0}$, and the basic translog model with demographics results if we set just $\boldsymbol{\mu}=\mathbf{0}$. The generalized translog model results if we set just $\mathbf{N}=\mathbf{0}$. The generalized translog model is essentially a translog model with a constant term included among the demographic variables.

## - Example 4

We first fit a basic translog model to our food consumption data, controlling for the number of children and adults in each household. We will also store these estimation results so we can use them later.

```
. use https://www.stata-press.com/data/r18/food_consumption

We specified the nocoeftable option to suppress the coefficient table and the elasticities (expenditure) option to obtain expenditure elasticities. Finally, we used the labels() option to name our five goods. Had we not done that, then the output would simply have numbered the goods from one to five.

For comparison's sake, we also fit the equivalent generalized translog model. We note that despite the long commands, the following one differs from the previous by just one character:

```
. demandsys gtranslog w_dairy w_proteins w_fruitveg w_flours w_misc,
> prices(p_dairy p_proteins p_fruitveg p_flours p_misc)
> demographics(n_kids n_adults)
> labels("dairy proteins fruitveg flours misc")
> expenditure(expfd) elasticities(expenditure) nolog nocoeftable

```
. estimates store gtranslog
```

The $R^{2}$ statistics from the generalized translog model are trivially higher than for the basic translog model. Because demandsys is based on maximum likelihood estimation and because the translog model is nested within the generalized translog model, we can use a likelihood-ratio test to see whether the inclusion of committed quantities is warranted here.

```
. lrtest gtranslog translog
Likelihood-ratio test
Assumption: translog nested within gtranslog
    LR chi2(5) = 59.00
Prob > chi2 = 0.0000
```

The generalized translog model adds additional $G$ parameters over the basic translog model, so the $\chi^{2}$ statistic has five degrees of freedom in this example. The result indicates that the use of the generalized version of the translog model is warranted. Of course, if you do this test for your own models, you must use the same demographic specification in both.

As we cautioned with the LES, interpreting the $\mu$ parameters of the generalized translog model as subsistence quantities requires care. We do not force the estimates to be positive, nor does demandsys check that $\sum_{g} p_{g i}\left(\mu_{g}+\boldsymbol{\nu}_{g}^{\prime} \mathbf{d}_{i}\right) \leq m_{i}$ for each observation $i$ in the dataset or that $\mu_{g}+\nu_{g}^{\prime} \mathbf{d}_{i} \geq 0$ for each observation and each good, both of which must be true if the subsistence argument is to be credible. We have noted that the generalized translog model can produce negative estimates of $\mu$ 's quite frequently and changing the demographic specification is often enough to produce negative estimates.

For example, if we refit the previous example controlling for just the number of children but not the number of adults, we obtain negative estimates for some of the $\mu$ parameters:

```
. demandsys gtranslog w_dairy w_proteins w_fruitveg w_flours w_misc,
> prices(p_dairy p_proteins p_fruitveg p_flours p_misc)
> demographics(n_kids) expenditure(expfd) nolog

Here, again, we see factor-variable notation for the parameter matrix $\mathbf{N}$ but also for $\boldsymbol{\Gamma}$. As we mentioned before, you should not interpret the factor-variable notation as you would in a regression output. We see the estimate labeled $1 \# 2$ under Good_g\#Good_h. This is the estimate of $\gamma_{12}$, the coefficient associated with $\ln p_{2} / \bar{m}$ in the equation for Good 1.

## AIDS

One of the most commonly used demand systems is the celebrated AIDS model of Deaton and Muellbauer (1980b). Among other benefits, the AIDS model can be viewed as a first-order approximation to any demand system. Historically, the AIDS model was also favored because it is "almost linear" in the sense that replacing the price index with an approximation results in share equations that are linear. Given the speed with which computers can fit nonlinear systems of equations, we do not implement that approximation.

An additional nice property of the AIDS model is that the functional form for its budget shares is a member of the "price-independent generalized log-linear" and the broader "price-independent generalized linear" families. An advantage to price-independent generalized linear expenditure shares is that they satisfy certain conditions required for the existence of a representative consumer and the related theory of aggregation. In short, expenditure shares of this form can be fit to data aggregated across consumers. The implied market demand curves are consistent with a single utility-maximizing
representative agent and satisfy the same conditions like Slutsky symmetry that hold for demand curves implied by a single consumer's utility-maximizing behavior. For more on price-independent generalized linear demands, see, for example, Muellbauer (1975), Lewbel (1989), and Pollak and Wales (1992, chap. 2).

The starting point for the AIDS model is the expenditure function

$$
\begin{equation*}
\ln e\left(\mathbf{p}, u ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}\right)=(1-\ln u) \ln a(\mathbf{p})+\ln u\{\ln a(\mathbf{p})+b(\mathbf{p})\} \tag{2}
\end{equation*}
$$

where $u$ is utility, the price index $\ln a(\mathbf{p})$ is defined as

$$
\ln a(\mathbf{p}) \equiv \alpha_{0}+\sum_{g} \alpha_{g} \ln p_{g}+\frac{1}{2} \sum_{g} \sum_{h} \gamma_{g h} \ln p_{g} \ln p_{h}
$$

where $p_{g}$ is the price of good $g$, and the price aggregator $b(\mathbf{p})$ is defined as

$$
b(\mathbf{p}) \equiv \beta_{0} \prod_{g} p_{g}^{\beta_{g}}
$$

Parameter $\beta_{0}$ cannot be distinguished from $u$, so we take $\beta_{0}=1$ in the following. In their original formulation, Deaton and Muellbauer (1980b) wrote their expenditure function slightly differently, with $u$ in place of $\ln u$ in (2). We have chosen to use $\ln u$ to draw some comparisons with the QUAIDS model later, and because utility is an ordinal concept, it will not affect the expenditure-share equations.

Suppose that all prices are equal to one. Then (2) with $\beta_{0}=1$ implies that $\ln e(p, u)=\alpha_{0}$. Thus, $\exp \left(\alpha_{0}\right)$ can be interpreted as the level of expenditure needed for minimal subsistence when all prices are equal to one. In practice, estimating $\alpha_{0}$ is difficult, particularly when prices are correlated, as they often are. Therefore, by default, we set $\alpha_{0}$ equal to the natural logarithm of the minimum level of expenditure in the estimation sample. You can override the default by specifying the piconstant() option. Of course, prices are generally not all equal to one, so you will want to try various values for $\alpha_{0}$ to see how sensitive elasticities and other calculations you may perform are to its value.

Expenditure functions consistent with rational consumer choice must be homogeneous of degree one in prices and expenditure, which imply that we must have $\sum_{g} \alpha_{g}=1, \sum_{g} \beta_{g}=0$, and $\sum_{g} \gamma_{g h}=\sum_{h} \gamma_{g h}=0$. Slutsky symmetry further requires that $\gamma_{g h}=\gamma_{h g}$ for all $g$ and $h$. Note that demandsys imposes these restrictions on the model being fit. An alternative is to fit the model with and without one or more of those restrictions and then test whether they hold. However, such unrestricted models can often fail to converge because of the increased number of parameters or because the models are "too flexible" and contain unidentifiable parameters.

Shephard's (1970) lemma equates the Hicksian demand functions with the partial derivatives of the expenditure function with respect to the price of the goods. Using Shephard's lemma, we can write the expenditure-share functions as

$$
\begin{equation*}
w_{g}\left(\mathbf{p}, m ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}\right)=\alpha_{g}+\sum_{h} \gamma_{g h} \ln p_{h}+\beta_{g} \ln \left\{\frac{m}{a(\mathbf{p})}\right\} \tag{3}
\end{equation*}
$$

Notice the simplicity of these share equations. Good $g$ 's expenditure share depends linearly on the $\log$ prices of all the goods as well as the $\log$ of an expenditure term. The expenditure term $m / a(\mathbf{p})$ essentially adjusts each household's expenditure to control the cost of living faced by that household. This term is sometimes referred to as deflated expenditure. Equation (3) also makes clear that luxury goods have $\beta_{g}>1$ while necessities have $\beta_{g}<1$; inferior goods have $\beta_{g}<0$.

Setting $e(\mathbf{p}, u)=m$ and manipulating (2) yields the indirect utility function

$$
\begin{equation*}
\ln v\left(\mathbf{p}, m ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}\right)=\frac{\ln m-\ln a(\mathbf{p})}{b(\mathbf{p})} \tag{4}
\end{equation*}
$$

We will come back to this equation below. We show how the indirect utility function plays a role in computing welfare measures in $[R]$ demandsys postestimation.

## QUAIDS

The Engel curves for the AIDS model have the so-called "Working-Leser" form after Working (1943) and Leser (1963),

$$
w_{g}=\omega_{g}+\psi_{g} \ln m
$$

so that the share of expenditures spent on good $g$ is a linear function of the logarithm of total expenditures. Banks, Blundell, and Lewbel (1997) provided evidence that in fact linear Engel curves provide a poor fit for many goods. They therefore consider Engel curves with an additional expenditure term,

$$
\begin{equation*}
w_{g}=A_{g}(\mathbf{p})+B_{g}(\mathbf{p}) \ln \left\{\frac{m}{a(\mathbf{p})}\right\}+C_{g}(\mathbf{p}) f\left\{\frac{m}{a(\mathbf{p})}\right\} \tag{5}
\end{equation*}
$$

where $A_{g}(\mathbf{p}), B_{g}(\mathbf{p})$, and $C_{g}(\mathbf{p})$ are differentiable functions of prices and $f\{m / a(\mathbf{p})\}$ is a differentiable function of real expenditures. $a(\mathbf{p})$ is the same translog price index as in the AIDS model.

Lewbel (1991), building on the work of Gorman (1981), showed that any exactly aggregable demand system must have the form of (5) and that additional terms containing functions of $m / a(\mathbf{p})$ are not theoretically possible if exact aggregability is to hold. Lewbel (1991) termed demand systems of the form (5) as having rank three because there are three linearly independent terms; Gorman (1981) showed that the maximum rank of demand systems is three if exact aggregability is to hold. In contrast, the AIDS model has rank two.

Banks, Blundell, and Lewbel (1997) further showed that the only indirect utility functions consistent with rank-three expenditure-share equations like (5) have the form

$$
\ln v(\mathbf{p}, m)=\left[\left\{\frac{\ln m-\ln a(\mathbf{p})}{b(\mathbf{p})}\right\}^{-1}+\lambda(\mathbf{p})\right]^{-1}
$$

where in their application they use the same definitions for $a(\mathbf{p})$ and $b(\mathbf{p})$ as in the AIDS model and they take $\lambda(\mathbf{p})=\sum_{g} \lambda_{g} \ln p_{g}$ with $\sum_{g} \lambda_{g}=0$. As with the restrictions implied by economic theory for the AIDS model, demandsys imposes the restriction that the $\lambda$ 's sum to zero. Also notice that if we restrict $\lambda_{g}=0$ for all $g$, we are left with the indirect utility function for the AIDS model shown in (4).

Solving for $\ln m$ yields the cost function

$$
\ln e(\mathbf{p}, u)=\frac{b(\mathbf{p})}{\frac{1}{\ln u}-\lambda(\mathbf{p})}+\ln a(\mathbf{p})
$$

Applying Shephard's lemma, we have the expenditure-share functions

$$
w_{g}(\mathbf{p}, m ; \boldsymbol{\alpha}, \boldsymbol{\Gamma}, \boldsymbol{\Lambda})=\alpha_{g}+\sum_{h} \gamma_{g h} \ln p_{h}+\beta_{g} \ln \left\{\frac{m}{a(\mathbf{p})}\right\}+\frac{\lambda_{g}}{b(\mathbf{p})}\left[\ln \left\{\frac{m}{a(\mathbf{p})}\right\}\right]^{2}
$$

This equation also makes clear our earlier claim that if $\lambda_{g}=0$ for all $g$ then the QUAIDS model reduces to the AIDS model; see (3).

## Controlling for demographic factors

demandsys allows you to choose between two different methods of incorporating demographic characteristics into AIDS and QUAIDS. The first method is the same as we have used with demand systems we have already covered: Pollak and Wales's (1978) demographic translation. An added benefit of translation is that it allows us to introduce constant terms that might be interpreted as subsistence or committed quantities. A possible downside to demographic translation is that the intuition behind how demographic variables affect expenditure shares may not strike all users as entirely lucid. Essentially, demographic variables alter the level of subsistence for each household or observation. However, as we cautioned above in our discussion of the generalized translog model, there are no restrictions to force $\sum_{g} p_{g i}\left(\mu_{g}+\boldsymbol{\nu}_{g}^{\prime} \mathbf{d}_{i}\right) \leq m_{i}$, nor are there any restrictions to force $\left(\mu_{g}+\nu_{g}^{\prime} \mathbf{d}_{i}\right) \geq 0$.

The second method of incorporating demographics that demandsys implements is based on Ray (1983) and Poi (2002) and is known as demographic scaling. This method explicitly allows for demographic variables to have "scale" and "composition" effects on expenditures as we explain below. There are two possible downsides to demographic scaling. First, it does not allow one to incorporate subsistence quantities into the demand system. While one may be tempted to include a constant term in the list of demographic variables because that is essentially what demographic translation does to incorporate subsistence quantities, the resulting parameter estimates do not have such a clearcut interpretation. Second, in our experience, models that incorporate demographic scaling sometimes take many iterations to converge. Specifying fewer demographic characteristics may help achieve convergence. We think this method is more intuitive than demographic translation, but either method should prove adequate for most applications.

## Demographic translation

We have already discussed demographic translation in the context of the LES and the translog and generalized translog demand systems, so we will not show the details here. In Methods and formulas, we show the formula for the expenditure shares for the generalized QUAIDS model, and we discuss the parameter restrictions that give rise to the generalized AIDS model and their nongeneralized variants.
demandsys provides for four models in the AIDS family that can incorporate demographic variables via demographic translation: aids, quaids, gaids, and gquaids. The first two models do not allow for committed quantities, while the latter two represent generalized variants that do. The arguments in Pollak and Wales $(1992,75)$ suggest that the generalized variants are to be preferred because doing so ensures that a constant term is included in each demand equation (compare with share equation). Whether the constants allow for a subsistence interpretation is another matter, and in [R] demandsys postestimation, we provide an example of how to see whether that interpretation holds.

## Demographic scaling

demandsys also implements the demographic scaling method used by Ray (1983) for the AIDS model and extended by Poi (2002) to the QUAIDS model. For each consumer, we again have a $D$-length vector of demographic characteristics $\mathbf{d}$. Suppose $\mathbf{d}$ is the number of children in a household and we are modeling expenditures on household goods, rent, utilities, and food. Then the household's expenditures will presumably increase by virtue of there being more members in the household; call this the scale effect. Second, the consumption pattern of the household may shift as more money is spent on items consumed by children versus adults; think of that as a composition effect. Ray (1983) does this by writing the expenditure function as

$$
e(\mathbf{p}, \mathbf{d}, u)=e^{R}(\mathbf{p}, u) \bar{m}_{0}(\mathbf{d}) \phi(\mathbf{p}, \mathbf{d}, u)
$$

Here $e^{R}(\mathbf{p}, u)$ is the expenditure function for a reference household, where $\mathbf{d}=0 . \bar{m}_{0}(\mathbf{d})$ increases total expenditure of the household and accounts for the scale effect. $\phi(\mathbf{p}, \mathbf{d}, u)$ controls for composition effects. For AIDS, Ray (1983) controlled for both of these effects by taking

$$
\bar{m}_{0}(\mathbf{d})=1+\rho^{\prime} \mathbf{d}
$$

for $G \times 1$ parameter vector $\rho$ and

$$
\phi(\mathbf{p}, \mathbf{d}, u)=\exp \left\{u \prod_{i} p_{g}^{\beta_{g}}\left(\prod_{g} p_{g}^{\boldsymbol{\eta}_{g} \mathbf{d}}-1\right)\right\}
$$

where $\boldsymbol{\eta}_{g}$ is the $g$ th row of $G \times D$ parameter matrix $\mathbf{H}$. In Methods and formulas, we show that the expenditure-share functions for the AIDS model with demographic scaling are

$$
w_{g}\left(\mathbf{p}, m, \mathbf{d} ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}, \boldsymbol{\lambda}, \boldsymbol{\rho}, \mathbf{H}\right)=\alpha_{g}+\sum_{h} \gamma_{g h} \ln p_{h}+\left(\beta_{g}+\boldsymbol{\eta}_{i} \mathbf{d}\right) \ln \left\{\frac{m}{\bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho}) a(\mathbf{p})}\right\}
$$

Basically, the function $\bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho})$ acts to reduce the effective amount of money available for spending. If $\mathbf{d}$ represents a set of indicator variables for regions of a country, then $\bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho})$ is controlling for the cost of living in different regions of the country. The function $\phi(\mathbf{p}, \mathbf{d}, u)$ is to make each good's expenditure expansion path a function of the household's demographics. Rather than all households increasing their expenditure share of good $g$ by the same $\beta_{g}$ in response to a change in $m$, now their responses can vary by household composition.

For the QUAIDS model, we show in Methods and formulas that an appropriate choice for $\phi(\mathbf{p}, \mathbf{d}, u)$ leads to expenditure share equations

$$
\begin{aligned}

& +\frac{\lambda_{g}}{b(\mathbf{p}) c(\mathbf{p}, \mathbf{d})}\left[\ln \left\{\frac{m}{\bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho}) a(\mathbf{p})}\right\}\right]^{2}
\end{aligned}
$$

The models aids and quaids allow for demographic scaling. To request demographic scaling, rather than demographic translation, we specify the scaling suboption of the demographics() option, as the next example shows.

## > Example 5

Here we fit a QUAIDS model to our food consumption data, controlling for the numbers of children and adults in each household. We request that demographic scaling be used rather than the default demographic translation.

```

. estimates store quaids_s
Because the QUAIDS model with demographic scaling for a 5-good system with 2 demographic variables has 32 estimated parameters, we instructed demandsys to report expenditure elasticities rather than the estimated parameters. We draw your attention to this part of the command:

```
demographics(n_kids n_adults, scaling)
```

Notice that we specified the suboption scaling. Had we not included this suboption, then demandsys would have used demographic translation instead. Finally, we asked Stata to store these estimation results as quaids_s.

The header of the output shows that demandsys fit a QUAIDS model as requested and that our demographic variables were incorporated using demographic scaling. Take note of the line that reads

```
Price index constant = 1.615
```

In our discussion of the basic AIDS model, we discussed the price index $a(\mathbf{p})$ that includes a constant term $\alpha_{0}$. We discussed that when all prices are equal to one, then $\exp \left(\alpha_{0}\right)$ can be interpreted as the
level of expenditure needed for minimal subsistence. demandsys looked at our expenditure variable expfd and found that the minimum value within the estimation sample is $\$ 5.03$. It therefore set $\alpha_{0}=\ln 5.03=1.615$. You can specify your own value for $\alpha_{0}$ by using the piconstant () option, which stands for price index constant.

The QUAIDS model nests the AIDS model, so we can easily use a likelihood-ratio test to see whether the quadratic terms in the expenditure-share equations contribute to the explanatory power of the model. We include quietly to fit the corresponding aids model without displaying the results and store the estimation results:

```
. quietly demandsys aids w_dairy w_proteins w_fruitveg w_flours w_misc,
> prices(p_dairy p_proteins p_fruitveg p_flours p_misc)
> demographics(n_kids n_adults, scaling)
> labels("dairy proteins fruitveg flours misc") expenditure(expfd)
. estimates store aids_s
```

Because we specified quietly, we did not request expenditure elasticities. Doing so would have required Stata to do more computations that we would not have seen.

We now perform the likelihood-ratio test:

```
. lrtest quaids_s aids_s
Likelihood-ratio test
Assumption: aids_s nested within quaids_s
    LR chi2(4) = 36.58
Prob > chi2 = 0.0000
```

In this example, we reject the null hypothesis that the four free $\lambda$ parameters are jointly equal to zero. Hence, the use of the QUAIDS model instead of the linear AIDS model is justified here. (Recall that to satisfy the adding-up constraint, we impose $\sum_{g} \lambda_{g}=0$ so that in our example the fifth parameter is determined by the first four and is not estimated.)

When one conducts tests of one model versus another using the likelihood-ratio principle, the more restrictive model must be nested within the more general model. For example, each of the AIDS models implemented here is nested within the corresponding QUAIDS models, and the AIDS model with demographic translation is nested within the generalized AIDS model. But it would make no sense to fit a generalized AIDS model and compare it with a generalized translog model because one is not a restricted variant of the other. In Methods and formulas, we describe the most flexible variant within each class of demand system, and we describe the parameter restrictions that give rise to less flexible variants; using lrtest to choose among members within the same class is valid.

Also, for a likelihood-ratio test to be valid, the model specifications-apart from the component we are testing-must be identical. That is, the two models must include the same estimation sample, the same goods, and the same demographic specification, including the method by which demographic variables are introduced for AIDS and QUAIDS models. Moreover, for AIDS and QUAIDS models, you must use the same value for the price index constant $\alpha_{0}$. If you do not specify the piconstant () option, demandsys will use the same value, assuming you use the same estimation sample.

## > Example 6

In this example, we will fit a generalized QUAIDS model, again controlling for the number of children and adults. Because we are fitting a generalized model, the demographics will be incorporated via demographic translation. To demonstrate the use of the piconstant() option, we will specify $\alpha_{0}=3$.

```

We see in the header of the output that demandsys did set the price index constant $\alpha_{0}=3$ as per our request.

The $\mu$ parameter estimates are all greater than zero, but it is difficult to interpret them in isolation. Because we control for the number of children and the number of adults in each household, the $\mu$ parameters themselves would represent subsistence expenditure shares for a hypothetical household with neither any children nor any adults! In a somewhat technical example in $[\mathrm{R}]$ demandsys postestimation, we continue this example and show how to recover the estimated $\boldsymbol{\mu}$ and $\mathbf{N}$ parameters and then use those estimates to calculate the actual subsistence shares for each household. We then compare the calculated subsistence expenditures with actual expenditures to see whether the subsistence interpretation even holds.

## Epilogue

demandsys provides easy access to some of the most commonly used demand systems and their extensions. You can control for demographic characteristics. Options and postestimation commands make obtaining elasticities trivial.

Despite what may appear to be a thorough implementation, we have only scratched the surface. demandsys is designed for large cross-sectional datasets. The Rotterdam model of Theil (1965) and Barten (1966) and its extensions are widely used in the analysis of time-series data.

A frequent concern is that datasets often have expenditure shares that are zero for some households. Deaton and Irish (1984) is an early contribution to the literature on how to deal with zero shares. Heien and Wessells (1990) proposed a two-step Heckman estimation procedure, but it has been shown to lead to inconsistent estimates (Vermeulen 2001). Tauchmann (2010) provides an alternative Heckmantype estimator that is consistent. Shonkwiler and Yen (1999) proposed an alternative estimator for zero shares. See also Yen and Lin (2006) for yet another approach and Meyerhoefer, Ranney, and Sahn (2005), who develop an estimator that controls for censoring with panel data. More recently, Caro et al. (2021) have developed the community-contributed Stata command quaidsce, which provides an implementation of Schonkwiler and Yen's estimator.

All of our estimators treat price as an exogenous variable. There are multiple reasons why one may want to allow for endogenous prices. In the classical supply and demand setting, which may occur for example in small villages, there are a small number of buyers and sellers, so the decisions that buyers make will influence prices, causing them to be endogenous in expenditure-share equations. A more pertinent concern is that prices may be measured with error. Consumption is often collected by survey data, and consumers are often not able to recall the exact price paid for an item. Unobserved quality differences also cause prices to be measured with error, especially when the goods being modeled are aggregates of individual items. For example, you may purchase filet mignon every week, while I purchase economy-grade ground beef. Both items are lumped together as "meat" even though, arguably, the two products are not even close substitutes; Nelson (1991) considers this type of problem. Spatial patterns may also make prices endogenous; see Case (1991) as an example.

Lecocq and Robin (2015) provide a community-contributed command called aidsills that allows one to fit an AIDS model with endogenous variables. Their command, however, provides the AIDS and QUAIDS models with only one method of including demographic variables that is similar to the demographic translation approach used here.

We have presented the QUAIDS model as somewhat of an endpoint because it has rank 3, which Gorman (1981) and Lewbel (1991) showed is the maximum rank of an exactly aggregable demand system. Lewbel and Pendakur (2009) develop what they call a theory of "implicit Marshallian demands" that are not within the class of demand equations considered by Gorman and Lewbel and hence can have any rank. Lewbel and Pendakur propose a demand system they call the exact affine Stone index that allows for interactions between prices and expenditures and allows for much more flexible Engel curves. Their empirical application shows that observed demands often deviate from those implied by demands that are linear or quadratic in income. Moreover, their model can be fit using the generalized method of moments, so the possibility of controlling for price endogeneity exists.

## Methods and formulas

Methods and formulas are presented under the following headings:
Introduction
LES
Generalized translog
QUAIDS with demographic translation
QUAIDS with demographic scaling
Estimation

## Introduction

As in the text in Remarks and examples, we continue to use subscript $i=1, \ldots, N$ to index observations, $g=1, \ldots, G$ to index goods, and $d=1, \ldots, D$ to index demographic variables. In formulas where we must use double summations across goods, we use $h=1, \ldots, G$ and $j=1, \ldots, G$ to index goods. We omit the observation subscript for most of this discussion; all variables and expressions without $i$ subscripts implicitly refer to the $i$ th observation. Only when we sum across observations do we make the $i$ subscript explicit.

Let $w_{g}$ be the expenditure share for good $g$ defined as $w_{g} \equiv\left(p_{g} q_{g}\right) / m$, where $p_{g}$ is the price of good $g, q_{g}$ is the quantity of good $g$ consumed, and $m$ denotes total expenditure on all the goods in the system being modeled. We use $\mathbf{w}, \mathbf{p}$, and $\mathbf{q}$ to represent the $G \times 1$ vectors of expenditure shares, prices, and quantities for observation $i$. Let $\mathbf{d}$ represent the $D \times 1$ vector of demographic characteristics.

We use the notation $w_{g}$ to denote the observed expenditure share for good $g$ for observation $i$. We use the notation $w_{g}(\mathbf{p}, m ; \boldsymbol{\theta})$ to represent an expenditure-share functions where we will replace generic parameter vector $\boldsymbol{\theta}$ with each model's parameter vectors and matrices. We adorn direct and indirect utility functions and expenditure functions analogously.

We use the notation $E_{h}^{g}$ to denote the uncompensated (Marshallian) elasticity of the quantity of good $g$ with respect to the price of good $h$. We use the notation $E^{g}$ to note the expenditure elasticity of good $g$. Then, given the definition of $w_{g}$, one can easily verify the following facts that are useful in obtaining the formulas for the elasticities:

$$
\begin{aligned}
& E^{g}=\frac{1}{w_{g}} \frac{\partial w_{g}}{\partial \ln m}+1=\frac{m}{w_{g}} \frac{\partial w_{g}}{\partial m}+1 \\
& E_{g}^{g}=\frac{1}{w_{g}} \frac{\partial w_{g}}{\partial \ln p_{g}}-1=\frac{p_{g}}{w_{g}} \frac{\partial w_{g}}{\partial p_{g}}-1 \\
& E_{h}^{g}=\frac{1}{w_{g}} \frac{\partial w_{g}}{\partial \ln p_{h}}=\frac{p_{h}}{w_{g}} \frac{\partial w_{g}}{\partial p_{h}}
\end{aligned}
$$

The Slutsky equation can be written in elasticity form to obtain the compensated (Hicksian) elasticity of the quantity of good $g$ with respect to the price of good $h: \widetilde{E}_{h}^{g}=E^{g} \widehat{w}_{h}+E_{h}^{g}$, where $\widehat{w}_{h}$ is the predicted expenditure share for good $h$. We discuss elasticities in more detail, including why we use $\widehat{w}_{h}$ rather than $w_{h}$, in [ R$]$ demandsys postestimation.

For each demand system, we provide the equations for the $g$ th expenditure share, the direct utility function (if available), the indirect utility function, the expenditure function (if available), and the elasticities of the quantity of good $g$ with respect to expenditure and the price of good $h$. Predicted values of the first four items are available via predict; the elasticities are available via estat elasticities. When one demand system is nested within a more general demand system, we provide the equations for only the more general demand system and note what parameter restrictions would result in the less general demand system. Moreover, we include demographic variables in our exposition; versions of models without demographic variables result when the corresponding parameter vectors and matrices are set to zero. We also note what parameter restrictions are imposed at estimation to ensure adding up, homogeneity, and Slutsky symmetry.

## LES

Let $c_{g}=\mu_{g}+\boldsymbol{\nu}_{g} \mathbf{d}$, where $\boldsymbol{\nu}_{g}$ is the $g$ th row of $G \times D$ parameter matrix $\mathbf{N}$. The LES begins with the utility function

$$
u(\mathbf{q}, \mathbf{d} ; \boldsymbol{\beta}, \boldsymbol{\mu}, \mathbf{N})=\prod_{g}\left(q_{g}-c_{g}\right)^{\beta_{g}}
$$

Utility maximization yields the expenditure-share equations

$$
w_{g}(\mathbf{p}, m, \mathbf{d} ; \boldsymbol{\beta}, \boldsymbol{\mu}, \mathbf{N})=\frac{p_{g} c_{g}}{m}+\beta_{g}\left(1-\sum_{h} \frac{p_{h} c_{h}}{m}\right)
$$

To enforce adding up, we impose the constraint $\sum_{g} \beta_{g}=1$. Slutsky symmetry and homogeneity are implied by the functional form of the LES model. Straightforward algebra shows the indirect utility function is

$$
v(\mathbf{p}, m, \mathbf{d} ; \boldsymbol{\beta}, \boldsymbol{\mu}, \mathbf{N})=\frac{\prod_{g} \beta_{g}^{\beta_{g}}}{\prod_{g} p_{g}^{\beta_{g}}}\left(m-\sum_{g} p_{g} c_{g}\right)
$$

and inverting provides the expenditure function

$$
e(\mathbf{p}, u, \mathbf{d} ; \boldsymbol{\beta}, \boldsymbol{\mu}, \mathbf{N})=u \frac{\prod_{g} p_{g}^{\beta_{g}}}{\prod_{g} \beta_{g}^{\beta_{g}}}+\sum_{g} p_{g} c_{g}
$$

The expenditure and uncompensated price elasticities are given by

$$
\begin{aligned}
& E^{g}=\frac{\beta_{g} m}{p_{g} c_{g}+\beta_{g}\left(m-\sum_{h} p_{h} c_{h}\right)} \\
& E_{h}^{g}= \begin{cases}\frac{p_{g} c_{g}\left(1-\beta_{g}\right)}{p_{g} c_{g}+\beta_{g}\left(m-\sum_{h} p_{h} c_{h}\right)}-1 & g=h \\
\frac{-\beta_{g} p_{h} c_{h}}{p_{g} c_{g}+\beta_{g}\left(m-\sum_{h} p_{h} c_{h}\right)} & g \neq h\end{cases}
\end{aligned}
$$

The Cobb-Douglas demand system results if we set $\boldsymbol{\mu}=\mathbf{0}$. Models without demographics result if we set $\mathbf{N}=\mathbf{0}$.

## Generalized translog

Continuing to use $c_{g}=\mu_{g}+\nu_{g} \mathbf{d}$, we can obtain the generalized translog expenditure-share equations with demographics by first obtaining the regular translog expenditure-share equations and then applying translation with both a constant term and demographic characteristics to those expenditure-share equations to obtain

$$
\begin{aligned}
w_{g}(\mathbf{p}, m, \mathbf{d} ; \boldsymbol{\alpha}, \boldsymbol{\Gamma}, \boldsymbol{\mu}, \mathbf{N}) & =\frac{p_{g} c_{g}}{m}+\frac{\bar{m}}{m} \frac{\alpha_{g}+\sum_{h} \gamma_{g h} \ln \left(\frac{p_{h}}{\bar{m}}\right)}{1+\sum_{h} \sum_{j} \gamma_{h j} \ln \left(\frac{p_{j}}{\bar{m}}\right)} \\
\bar{m} & =m-\sum_{j} p_{j} c_{j}
\end{aligned}
$$

The normalization $\sum_{g} \alpha_{g}=1$ ensures the expenditure shares sum to 1 , and Slutsky symmetry requires that $\gamma_{j h}=\gamma_{h j}$. Homogeneity is implied by the functional form of the expenditure-share equation.

Noting that the translated indirect utility function has the same form as the untranslated version except with $\bar{m}$ replacing $m$, we have the indirect utility function

$$
\ln v(\mathbf{p}, m, \mathbf{d} ; \boldsymbol{\alpha}, \boldsymbol{\Gamma}, \boldsymbol{\mu}, \mathbf{N})=-\sum_{g} \alpha_{g} \ln \left(\frac{p_{g}}{\bar{m}}\right)-\frac{1}{2} \sum_{g} \sum_{h} \gamma_{g h} \ln \left(\frac{p_{g}}{\bar{m}}\right) \ln \left(\frac{p_{h}}{\bar{m}}\right)
$$

A limitation of the generalized translog model is that we cannot solve the indirect utility function for a closed-form expression for the cost function, nor does a closed-form expression for the direct utility function exist. (The direct utility function described in Christensen, Jorgenson, and Lau [1975] is not the utility function that is implied by their indirect utility function.)

Demand systems with translated demographics and committed quantities tend to produce elasticity formulas that are rather long. Omitting function arguments for clarity, we begin by writing the expenditure-share equation for good $g$ as

$$
w_{g}=A_{g}+B_{g} \times \frac{N_{g}}{D_{g}}
$$

where

$$
\begin{aligned}
A_{g} & =\frac{p_{g} c_{g}}{m} \\
B_{g} & =\frac{\bar{m}}{m}=1-\frac{\sum_{h} p_{h} c_{h}}{m} \\
N_{g} & =\alpha_{g}+\sum_{h} \gamma_{g h} \ln p_{h}-\ln \left(m-\sum_{h} p_{h} c_{h}\right) \sum_{h} \gamma_{g h} \\
D_{g} & =1+\sum_{j} \sum_{h} \gamma_{j h} \ln p_{h}-\ln \left(m-\sum_{h} p_{h} c_{h}\right) \sum_{j} \sum_{h} \gamma_{j h}
\end{aligned}
$$

Applying the chain and quotient rules of elementary calculus, we have

$$
\frac{\partial w_{g}}{\partial m}=\frac{\partial A_{g}}{\partial m}+B_{g}\left(\frac{D_{g} \frac{\partial N_{g}}{\partial m}-N_{g} \frac{\partial D_{g}}{\partial m}}{D_{g}^{2}}\right)+\frac{N_{g}}{D_{g}} \frac{\partial B_{g}}{\partial m}
$$

where

$$
\begin{aligned}
\frac{\partial A_{g}}{\partial m} & =-\frac{p_{g} c_{g}}{m^{2}} & \frac{\partial B_{g}}{\partial m} & =\frac{\sum_{h} p_{h} c_{h}}{m^{2}} \\
\frac{\partial N_{g}}{\partial m} & =-\frac{1}{m-\sum_{h} p_{h} c_{h}} \sum_{h} \gamma_{g h} & \frac{\partial D_{g}}{\partial m} & =-\frac{1}{m-\sum_{h} p_{h} c_{h}} \sum_{j} \sum_{h} \gamma_{j h}
\end{aligned}
$$

Given $\partial w_{g} / \partial m$, the expenditure elasticity of good $g$ is calculated as $E^{g}=\left(m / \widehat{w}_{g}\right)\left(\partial w_{g} / \partial m\right)+1$. We also have

$$
\frac{\partial w_{g}}{\partial p_{h}}=\frac{\partial A_{g}}{\partial p_{h}}+B_{g}\left(\frac{D_{g} \frac{\partial N_{g}}{\partial p_{h}}-N_{g} \frac{\partial D_{g}}{\partial p_{h}}}{D_{g}^{2}}\right)+\frac{N_{g}}{D_{g}} \frac{\partial B_{g}}{\partial p_{h}}
$$

where

$$
\begin{aligned}
& \frac{\partial A_{g}}{\partial p_{h}}= \begin{cases}c_{g} / m & h=g \\
0 & h \neq g\end{cases} \\
& \frac{\partial B_{g}}{\partial p_{h}}=-\frac{c_{g}}{m} \\
& \frac{\partial N_{g}}{\partial p_{h}}=\frac{\gamma_{g h}}{c_{h}}+\frac{c_{h}}{m-\sum_{j} p_{j} c_{j}} \sum_{j} \gamma_{g j} \\
& \frac{\partial D_{g}}{\partial p_{h}}=\frac{1}{p_{h}} \sum_{j} \gamma_{j h}+\frac{c_{h}}{m-\sum_{j} p_{j} c_{j}} \sum_{j k} \gamma_{j k}
\end{aligned}
$$

Given $\partial w_{g} / \partial p_{h}$, the uncompensated price elasticity of good $g$ with respect to price $h$ is calculated as $E_{h}^{g}=\left(p_{h} / w_{g}\right)\left(\partial w_{g} / \partial p_{h}\right)+\mathbb{I}_{h=g}$, where $\mathbb{I}_{x}$ is the indicator function that takes on the value one if $x$ is true and zero otherwise.

The basic translog results if we set $\boldsymbol{\mu}=\mathbf{0}$, and models without demographics have $\mathbf{N}=\mathbf{0}$.

## QUAIDS with demographic translation

Translating Banks, Blundell, and Lewbel's (1997) indirect utility function, we have

$$
\begin{aligned}
\ln V\left(\mathbf{p}, m, \mathbf{d} ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}, \boldsymbol{\lambda}, \boldsymbol{\mu}, \mathbf{N}\right) & =\left[\left\{\frac{\ln \bar{m}-\ln a(\mathbf{p})}{b(\mathbf{p})}\right\}^{-1}+\lambda(\mathbf{p})\right]^{-1} \\
\ln (\mathbf{p}) & =\alpha_{0}+\sum_{g} \alpha_{g} \ln p_{g}+\frac{1}{2} \sum_{g} \sum_{h} \gamma_{g h} \ln p_{g} \ln p_{h} \\
b(\mathbf{p}) & =\prod_{g} p_{g}^{\beta_{g}} \\
\lambda(\mathbf{p}) & =\sum_{g} \lambda_{g} \ln p_{g}
\end{aligned}
$$

where $\alpha_{0}$ is the value specified in the piconstant() option. Solving for $\bar{m}$ and recalling that $m=\bar{m}+\sum_{g} p_{g} c_{g}$ for $c_{g}=\mu_{g}+\nu_{g} d$, we have the expenditure function

$$
\begin{equation*}
e\left(\mathbf{p}, u, \mathbf{d} ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}, \boldsymbol{\lambda}, \boldsymbol{\mu}, \mathbf{N}\right)=\exp \left\{\frac{b(\mathbf{p}) \ln u}{1-\lambda(\mathbf{p}) \ln u}+\ln a(\mathbf{p})\right\}+\sum_{g} p_{g} c_{g} \tag{6}
\end{equation*}
$$

Applying Shepherd's lemma yields the expenditure-share equations

$$
\begin{align*}
& w_{g}\left(\mathbf{p}, m, \mathbf{d} ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}, \boldsymbol{\lambda}, \boldsymbol{\mu}, \mathbf{N}\right)= \\
& \frac{p_{g} c_{g}}{m}+\frac{\bar{m}}{m}\left(\alpha_{g}+\sum_{h} \gamma_{g h} \ln p_{h}+\beta_{g} \ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}+\frac{\lambda_{g}}{b(\mathbf{p})}\left[\ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}\right]^{2}\right) \tag{7}
\end{align*}
$$

To obtain the expenditure elasticities, we first write (7) as

$$
\begin{equation*}
w_{g}=R_{g}+S_{g} \times T_{g} \tag{8}
\end{equation*}
$$

where

$$
\begin{aligned}
& R_{g}=\frac{p_{g} c_{g}}{m} \quad S_{g}=\frac{\bar{m}}{m} \\
& T_{g}=\alpha_{g}+\sum_{h} \gamma_{g h} \ln p_{h}+\beta_{g} \ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}+\frac{\lambda_{g}}{b(\mathbf{p})}\left[\ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}\right]^{2}
\end{aligned}
$$

Taking the derivative with respect to $\ln m$, we have

$$
\frac{\partial w_{g}}{\partial \ln m}=\frac{\partial R_{g}}{\partial \ln m}+S_{g} \frac{\partial T_{g}}{\partial \ln m}+T_{g} \frac{\partial S_{g}}{\partial \ln m}
$$

where

$$
\begin{aligned}
\frac{\partial R_{g}}{\partial \ln m} & =-\frac{p_{g} c_{g}}{m} \quad \frac{\partial S_{g}}{\partial \ln m}=1-S_{g} \\
\frac{\partial T_{g}}{\partial \ln m} & =\frac{1}{S_{g}}\left[\beta_{g}+2 \frac{\lambda_{g}}{b(\mathbf{p})} \ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}\right]
\end{aligned}
$$

Then the expenditure elasticity for good $g$ is given by $E^{g}=\left(1 / w_{g}\right)\left(\partial w_{g} / \partial \ln m\right)+1$.

To obtain the uncompensated price elasticity of good $g$ with respect to price $h$, we again use (8). Taking the partial derivative with respect to $\ln p_{h}$, we have

$$
\frac{\partial w_{g}}{\partial \ln p_{h}}=\frac{\partial R_{g}}{\partial \ln p_{h}}+S_{g} \frac{\partial T_{g}}{\partial \ln p_{h}}+T_{g} \frac{\partial S_{g}}{\partial \ln p_{h}}
$$

The required partials are

$$
\begin{aligned}
\frac{\partial R_{g}}{\partial \ln p_{h}} & = \begin{cases}\frac{p_{h} c_{h}}{m} & h=g \\
0 & h \neq g\end{cases} \\
\frac{\partial S_{g}}{\partial \ln p_{h}} & =-\frac{p_{h} c_{h}}{m} \\
\frac{\partial T_{g}}{\partial \ln p_{h}} & =\gamma_{g h}+\beta_{g} \frac{\partial}{\partial \ln p_{h}}\left[\ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}\right]+\frac{\partial}{\partial \ln p_{h}}\left(\frac{\lambda_{g}}{b(\mathbf{p})}\left[\ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}\right]^{2}\right)
\end{aligned}
$$

where

$$
\begin{aligned}
\frac{\partial}{\partial \ln p_{h}}\left[\ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}\right]= & -\left(\frac{p_{h} c_{h}}{m-\sum_{j} p_{j} c_{j}}+\alpha_{h}+\sum_{j} \gamma_{h j} \ln p_{j}\right) \\
\frac{\partial}{\partial \ln p_{h}}\left(\frac{\lambda_{g}}{b(\mathbf{p})}\left[\ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}\right]^{2}\right)= & 2 \frac{\lambda_{g}}{b(\mathbf{p})} \ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\} \frac{\partial}{\partial \ln p_{h}}\left[\ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}\right] \\
& -\frac{\lambda_{g} \beta_{h}}{b(\mathbf{p})}\left[\ln \left\{\frac{\bar{m}}{a(\mathbf{p})}\right\}^{2}\right]
\end{aligned}
$$

The uncompensated price elasticity of good $g$ with respect to price $h$ is $E_{h}^{g}=\left(p_{h} / w_{g}\right)\left(\partial w_{g} / \partial p_{h}\right)+$ $\mathbb{I}_{h=g}$.

The AIDS model results if $\boldsymbol{\lambda}=\mathbf{0}$. The nongeneralized variants result if $\boldsymbol{\mu}=\mathbf{0}$. The variants without demographics result if $\mathbf{N}=\mathbf{0}$.

## QUAIDS with demographic scaling

As can be gleaned from (6), the expenditure function for a QUAIDS model without any form of translation or scaling is

$$
\begin{aligned}
e\left(\mathbf{p}, u ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}, \boldsymbol{\lambda}\right) & =\exp \left\{\frac{b(\mathbf{p}) \ln u}{1-\lambda(\mathbf{p}) \ln u}+\ln a(\mathbf{p})\right\}=\exp \left\{\frac{b(\mathbf{p})}{\frac{1}{\ln u}-\lambda(\mathbf{p})}+\ln a(\mathbf{p})\right\} \\
a(\mathbf{p}) & =\alpha_{0}+\sum_{j} \alpha_{j} \ln p_{j}+\frac{1}{2} \sum_{j} \sum_{k} \gamma_{j k} \ln p_{j} \ln p_{k} \\
b(\mathbf{p}) & =\prod_{j} p_{j}^{\beta_{j}} \\
\lambda(\mathbf{p}) & =\sum_{j} \lambda_{j} \ln p_{j}
\end{aligned}
$$

The AIDS case results when $\boldsymbol{\lambda}=\mathbf{0}$, and we obtain the expenditure function given by (2).

To implement Ray's (1983) demographic scaling as extended to the QUAIDS case in Poi (2002), we require a function that can be split into two parts, one part that depends on prices and utility and one part that does not:

$$
m_{0}(\mathbf{p}, u, \mathbf{d})=\bar{m}_{0}(\mathbf{d}) \phi(\mathbf{p}, \mathbf{d}, u)
$$

For $\bar{m}_{0}(\mathbf{d})$, we use the same function as in Ray,

$$
\bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho})=1+\boldsymbol{\rho}^{\prime} \mathbf{d}
$$

where $\boldsymbol{\rho}$ is a $D \times 1$ parameter vector. For $\phi(\mathbf{p}, \boldsymbol{\delta}, u)$, we follow Poi (2002) and use

$$
\phi(\mathbf{p}, \mathbf{d}, u ; \boldsymbol{\beta}, \boldsymbol{\lambda}, \mathbf{H})=\exp \left\{\frac{b(\mathbf{p})\left(\prod_{j} p_{j}^{\boldsymbol{\eta}_{j}{ }^{\mathbf{d}}}-1\right)}{\frac{1}{\ln u}-\lambda(\mathbf{p})}\right\}
$$

where $\boldsymbol{\eta}_{j}$ is the $j$ th row of $G \times D$ parameter matrix $\mathbf{H}$. For AIDS when $\boldsymbol{\lambda}=0$, we are left with the function used by Ray (1983). The expenditure function for the QUAIDS model with demographic scaling is then

$$
e\left(\mathbf{p}, u, \mathbf{d} ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}, \boldsymbol{\lambda}, \boldsymbol{\rho}, \mathbf{H}\right)=e\left(\mathbf{p}, u ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}, \boldsymbol{\lambda}\right) \times \bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho}) \times \phi(\mathbf{p}, \mathbf{d}, u ; \boldsymbol{\beta}, \mathbf{H})
$$

Applying Shepherd's lemma, we have the share equations

$$
\begin{aligned}
& w_{g}\left(\mathbf{p}, m, \mathbf{d} ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\Gamma}, \boldsymbol{\lambda}, \boldsymbol{\rho}, \mathbf{H}\right)= \\
& \alpha_{g}+\sum_{h} \gamma_{g h} \ln p_{h}+\left(\beta_{g}+\boldsymbol{\eta}_{g} \mathbf{d}\right) \ln \left[\frac{m}{\bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho}) a(\mathbf{p})}\right]+\frac{\lambda_{g}}{b(\mathbf{p}) c(\mathbf{p}, \mathbf{d})}\left[\ln \left\{\frac{m}{\bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho}) a(\mathbf{p})}\right\}\right]^{2}
\end{aligned}
$$

where the demographic-adjusted price aggregator is defined as $c(\mathbf{p}, \mathbf{d}) \equiv \prod_{j} p_{j}^{\boldsymbol{\eta}_{j} \mathbf{d}}$. The indirect utility function is

$$
\ln V\left(\mathbf{p}, m, \mathbf{d} ; \alpha_{0}, \boldsymbol{\alpha}, \boldsymbol{\beta}, \boldsymbol{\gamma}, \boldsymbol{\lambda}, \boldsymbol{\rho}, \mathbf{H}\right)=\left[\frac{b(\mathbf{p}) c(\mathbf{p}, \mathbf{d})}{\ln \left\{m-\bar{m}_{0}(\mathbf{d} ; \boldsymbol{\rho})-a(\mathbf{p})\right\}}+\lambda(\mathbf{p})\right]^{-1}
$$

Because we are not dealing with demographic translation here, the partial derivatives required for elasticities are not as involved as they are for the QUAIDS model with demographic translation or the generalized translog model. We have

$$
\frac{\partial w_{g}}{\partial \ln m}=\beta_{g}+\boldsymbol{\eta}_{g} \mathbf{d}+\frac{2 \lambda_{g}}{b(\mathbf{p}) c(\mathbf{p}, \mathbf{d})} \ln \left\{\frac{m}{\left(1+\boldsymbol{\rho}^{\prime} \mathbf{d}\right) a(\mathbf{p})}\right\}
$$

and

$$
\begin{aligned}
\frac{\partial w_{g}}{\partial \ln p_{h}}=\gamma_{g h} & -\left[\beta_{g}+\boldsymbol{\eta}_{g} \mathbf{d}+\frac{2 \lambda_{g}}{b(\mathbf{p}) c(\mathbf{p}, \mathbf{d})} \ln \left\{\frac{m}{\left(1+\boldsymbol{\rho}^{\prime} \mathbf{d}\right) a(\mathbf{p})}\right\}\right] \times\left(\alpha_{h}+\sum_{k} \gamma_{h k} \ln p_{k}\right) \\
& +\frac{\left(\beta_{h}+\boldsymbol{\eta}_{h} \mathbf{d}\right) \lambda_{g}}{b(\mathbf{p}) c(\mathbf{p}, \mathbf{d})}\left[\ln \left\{\frac{m}{\left(1+\boldsymbol{\rho}^{\prime} \mathbf{d}\right) a(\mathbf{p})}\right\}\right]^{2}
\end{aligned}
$$

The AIDS model with demographic scaling results if $\boldsymbol{\lambda}=0$, and models without demographic scaling result if $\boldsymbol{\rho}=\mathbf{0}$ and $\mathbf{H}=\mathbf{0}$.

## Estimation

The expenditure shares of a demand system represent a set of nonlinear seemingly unrelated regression (SUR) equations. Hence, estimation is performed using nlsur with just one complication. Our system of equations for observation $i$ and generic parameter vector $\boldsymbol{\theta}$ can be written as

$$
\begin{aligned}
w_{1 i} & =w_{1}\left(\mathbf{p}_{i}, m_{i}, \mathbf{d}_{i} ; \boldsymbol{\theta}\right)+\epsilon_{1 i} \\
w_{2 i} & =w_{2}\left(\mathbf{p}_{i}, m_{i}, \mathbf{d}_{i} ; \boldsymbol{\theta}\right)+\epsilon_{2 i} \\
\vdots & =\quad \vdots \\
w_{G i} & =w_{G}\left(\mathbf{p}_{i}, m_{i}, \mathbf{d}_{i} ; \boldsymbol{\theta}\right)+\epsilon_{G i}
\end{aligned}
$$

where $\boldsymbol{\epsilon}_{i}=\left(\epsilon_{1 i}, \epsilon_{2 i}, \ldots, \epsilon_{G i}\right)$ is a vector of zero-mean disturbances. Because $\sum_{g} w_{g i}=1$ and by the construction of our demand systems we also have $\sum_{g} w_{g}\left(\mathbf{p}_{i}, m_{i}, \mathbf{d}_{i} ; \boldsymbol{\theta}\right)=1$, it must be the case that $\sum_{g} \epsilon_{g i}=0$. Therefore, $\operatorname{det}(\boldsymbol{\Sigma})=\operatorname{det}\left\{E\left(\boldsymbol{\epsilon} \boldsymbol{\epsilon}^{\prime}\right)\right\}=\mathbf{0}$, and neither the (quasi)maximum likelihood estimator nor the feasible generalized nonlinear SUR estimator is defined.

Barten (1969) showed that to obtain a well-defined likelihood function, we can drop any one of the expenditure-share equations and fit the system containing the remaining $G-1$ equations. Parameter restrictions that force the demand system's equations to sum to 1 can then be used to recover the parameters of the dropped equation. demandsys drops the final equation from the demand system, but which equation is dropped should not concern you: Barten (1969) showed that you obtain the same likelihood function regardless of which one is dropped.

Moreover, the nonlinear SUR model satisfies the so-called Oberhofer-Kmenta (1974) conditions that allow us to cycle between estimating the parameters $\boldsymbol{\theta}$ and the error covariance matrix $\boldsymbol{\Sigma}$ as nlsur does when we specify option ifgnls. The upshot is that we fit our expenditure-share equations by calling nlsur with option ifgnls. The resulting parameter estimate $\widehat{\boldsymbol{\theta}}$ is the (quasi)maximum likelihood estimate of the parameters of our demand system. The $(G-1) \times(G-1)$ estimated error covariance matrix is returned in matrix e(Sigma).

Estimation weights, variance-covariance matrix options, and options to control the optimization process available with demandsys are simply passed to nlsur. See Methods and formulas in [R] nlsur.

When you type predict ..., shares eq(\#), you obtain the predicted shares for the \#th equation, based on the expenditure-share equation for the demand system estimated. By construction, the sum of predicted shares for each observation is equal to one.

When you type predict ..., residuals eq(\#), you obtain the residuals for the \#th equation defined as $r_{\# i}=w_{\# i}-\widehat{w_{\# i}}$, where $\widehat{w_{\# i}}$ is the predicted share for equation \# for observation $i$.

When you type predict..., quantities eq(\#), predict first computes the predicted shares $\widehat{w_{\# i}}$ and then computes $\widehat{q_{\# i}}=m_{i} \widehat{w_{\# i}} / p_{\# i}$.

When you type predict ..., iuf, predict evaluates the indirect utility function based on the formulas given above.

When you type predict ..., ef utilities $(u)$, predict evaluates the expenditure function based on the formulas given above at the levels of utility specified in variable $u$.

## Acknowledgment

We thank Brian Poi of Poi Consulting LLC, East Fallowfield, PA, for writing the popular communitycontributed quaids command, which motivated us to implement demandsys. We also thank Dr. Poi for his advice on and review of the demandsys command.

## Title

demandsys postestimation - Postestimation tools for demandsys

| Postestimation commands | predict | margins | estat |
| :--- | :--- | :--- | :--- |
| Remarks and examples | References | Also see |  |

## Postestimation commands

The following postestimation commands are of special interest after demandsys:

| Command | Description |
| :--- | :--- |
| estat elasticities | price and expenditure elasticities |
| estat parameters | estimated parameter vectors and matrices |

The following standard postestimation commands are also available:

| Command | Description |
| :--- | :--- |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian <br> information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) <br> cataloging estimation results |
| estimates | point estimates, standard errors, testing, and inference for linear combinations <br> of coefficients |
| lincom | likelihood-ratio test <br> marginal means, predictive margins, marginal effects, and average marginal <br> effects |
| margins | graph the results from margins (profile plots, interaction plots, etc.) <br> point estimates, standard errors, testing, and inference for nonlinear combi- <br> nations of coefficients |
| marginsplot | predicted shares, residuals, quantities, and functions <br> point estimates, standard errors, testing, and inference for generalized pre- <br> nlcomict |
| predictnl | Wald tests of simple and composite linear hypotheses <br> Wald tests of nonlinear hypotheses |
| test |  |

## predict

## Description for predict

predict creates a new variable containing statistics such as predicted shares and residuals based on the demandsys estimation results currently active.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic options]
```

statistic Description

Main

## shares

quantities
residuals
iuf
ef
options
Main
equation(\#eqno)
prices(varlist ${ }_{p}$ )
expenditures(varname)
utilities(varname)
demographics(varlist)
predicted shares; the default
predicted quantities
residuals
indirect utility function
expenditure function

Description
display only specified goods; available only with shares, quantities, and residuals
specify set of counterfactual price variables
specify a counterfactual total expenditure variable
specify the variable containing the utilities at which to compute the expenditure function; available only with and required with ef
specify a set of counterfactual demographic variables

## Options for predict

$\qquad$ Main
shares, the default, calculates the predicted shares.
quantities calculates the predicted quantities given actual prices, actual expenditures, and predicted shares.
residuals calculates the residuals.
iuf calculates the indirect utility function $v(\mathbf{p}, m)$.
ef calculates the expenditure function $e(\mathbf{p}, u)$. You must also specify option utilities() with this option. This option is not available after translog and generalized translog models.
equation(\#eqno) specifies to which good you are referring. equation(\#1) would mean the calculation is to be made for the first good, equation(\#2) would mean the second, and so on. If you do not specify equation(), results are the same as if you specified equation(\#1).
prices ( varlist $_{p}$ ) specifies a set of counterfactual price variables at which to compute the requested statistic. You must specify $G$ variables, where $G$ is the number of goods in the demand system. By default, predict uses the same price variables that were used to fit the demand system. This option aids in the computation of welfare and other policy measures by allowing you to contrast predicted values at different price levels.
expenditures (varname) specifies a counterfactual total expenditure variable at which to compute the requested statistic. By default, predict uses the same expenditure variable that was used to fit the demand system. This option aids in the computation of welfare and other policy measures by allowing you to contrast predicted values at different expenditure levels.
utilities (varname) specifies the variable containing the utilities at which the expenditure function is to be computed. Almost surely, varname is a variable that was created by calling predict ..., iuf .... This option aids in the computation of welfare and other policy measures by allowing you to contrast predicted values at different levels of utility.
demographics (varlist) specifies a set of counterfactual demographic variables at which to compute the requested statistic. If you specified $D$ demographic variables at estimation, then you must specify precisely $D$ variables here. By default, predict uses the same demographic variables (if any) that were used to fit the demand system.

## margins

## Description for margins

margins estimates margins for the predicted share of the first good.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

margins [, options]
margins, predict(statistic ...) [options]
statistic Description
shares
quantities
residuals
iuf indirect utility function
*ef expenditure function
*You must specify the predict option utilities() with statistic ef.
Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

## estat

## Description for estat

estat elasticities computes expenditure and price elasticities after fitting a demand system using demandsys. Elasticities are calculated at the price and expenditure levels in the data. However, you may compute elasticities at the means of prices and expenditures or use other counterfactual prices or expenditures.
estat parameters returns the estimated parameter vectors and matrices based on the currently active demandsys estimation results. Results are stored in $r$ () and vary depending on the demand model fitted. See [U] 18.8 Accessing results calculated by other programs.

## Menu for estat

Statistics $>$ Postestimation

## Syntax for estat

Compute price and expenditure elasticities

```
estat elasticities [if] [in], { expenditure|\underline{compensated|uncompensated }}
    [[atmeans|at(atspec)] generate(stub)]
```

Report estimated parameter vectors and matrices
estat parameters

## Options for estat elasticities

$\qquad$ Main
expenditure, compensated, and uncompensated indicate the type of elasticities to be reported. You must specify one of these.
expenditure requests that the $G$ expenditure elasticities be calculated, where $G$ is the number of goods in the system.
compensated requests that compensated price elasticities be calculated. There is a total of $G^{2}$ such elasticities because there are $G$ goods, each of whose quantity consumed can be affected by any one of the $G$ prices changing.
uncompensated requests that the $G^{2}$ uncompensated price elasticities be calculated.
atmeans requests that elasticities be calculated at the means of the price, expenditure, and demographic
variables. By default, elasticities are computed for each observation and then averaged.
at (atspec) specifies the prices, expenditures, and demographic variables' values at which elasticities are to be calculated. If you do not specify this option, elasticities are calculated at the observed values unless you specify option atmeans, in which case they are calculated at the means of the variables. See example 1 below. You may not specify option at () if you request compensated price elasticities.
generate (stub) requests that new variables be generated holding the observation-level elasticities. For expenditure elasticities, $G$ new variables $s t u b \_1$, stub_2, ..., stub_ $G$ will be created, where $G$ is the number of goods. For price elasticities, $G^{2}$ new variables will be created of the form stub_g_h for $g=1, \ldots, G$ and $h=1, \ldots, G$. Variable stub_ $g \_h$ will contain the percentage change in the quantity of good $h$ with respect to the price of good $g$.

## Remarks and examples

Remarks are presented under the following headings:

Introduction<br>Elasticities<br>Evaluating elasticities<br>Compensating and equivalent variation

## Introduction

estat elasticities allows you to compute expenditure and price elasticities after you fit a demand model and is much more flexible than the options available with demandsys to display elasticities in lieu of coefficient estimates. With estat elasticities, you can calculate elasticities at the same prices, expenditures, and demographic variables' levels as was used at estimation time, or you can specify your own values. For example, you could calculate price elasticities for every observation in your dataset assuming each household had two children, even if the number of children varies by household. Example 1 below shows you how that can be done.
predict allows you to obtain values of the indirect utility function and of the expenditure function underlying the demand system you fit. Example 3 leverages that ability and shows you how to compute compensated and equivalent variation in response to a price change.
estat parameters allows you to obtain the estimated parameter vectors and matrices for the demand system based on the coefficient vector stored in e(b). This may be useful if you wish to conduct further policy experiments or calculate your own welfare measures. For instance, in example 2 below, we show how estat parameters with just a bit of coding can be used to check whether a fitted generalized translog model can be interpreted as having subsistence quantities for each good.

## Elasticities

Although one can have demandsys report expenditure or price elasticities for the estimation sample, the estat elasticities command gives you much more flexibility. We illustrate features of estat elasticities in the next example. We often request expenditure elasticities to keep the output shorter, but all our commands would work regardless of the type of elasticity requested.

## > Example 1

Before we can obtain elasticities, we first need to fit a demand system to our data. Here we include the quietly prefix command to omit the results of fitting a quadratic almost ideal demand system (QUAIDS) model with demographic translation, and we use the labels() option to provide short names for each of our goods. We type

```
. use https://www.stata-press.com/data/r18/food_consumption
(Food consumption)
. quietly demandsys quaids w_dairy w_proteins w_fruitveg w_flours w_misc,
> prices(p_dairy p_proteins p_fruitveg p_flours p_misc)
> expenditures(expfd)
> demographics(n_kids n_adults)
> labels(Dairy Meats FruitVeg Flours Misc)
```

Suppose we want the average expenditure elasticity among households with two children. We type
. estat elasticities if n_kids == 2, expenditure

| Expenditure elasticities |  |  |  |  | Number of obs $=751$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Expenditure | Elasticity | Std. err. | z | $P>\|z\|$ | [95\% conf | interval] |
| Dairy | . 9028921 | . 0240869 | 37.48 | 0.000 | . 8556826 | . 9501016 |
| Meats | 1.087763 | . 0156852 | 69.35 | 0.000 | 1.05702 | 1.118505 |
| FruitVeg | . 9978958 | . 0215996 | 46.20 | 0.000 | . 9555614 | 1.04023 |
| Flours | . 8523383 | . 0220511 | 38.65 | 0.000 | . 8091189 | . 8955576 |
| Misc | . 9971274 | . 0265993 | 37.49 | 0.000 | . 9449938 | 1.049261 |

The header of the output reports that there are 751 households in the dataset with two children. Had we not specified the labels() option when we fit our model, estat elasticities would have simply numbered the goods from one through five.

What is displayed in the table of output is an average elasticity. Behind the scenes, estat elasticities calculated the five expenditure elasticities for each of the 751 households in this sample. What is reported as the expenditure elasticity for dairy products is the average over the 751 individual expenditure elasticities calculated. The column labeled Std. err. contains the standard error of the estimated mean. Looking to the right, we see the $95 \%$ confidence interval for the mean dairy elasticity is [0.856, 0.950]. More importantly, the column labeled Std. err . is not the sample standard deviation of the 751 individual elasticities, nor does the $95 \%$ confidence interval report something resembling the central $95 \%$ of the individual elasticities.

To save the individual elasticities for the 751 observations, you can use the generate() option like so:

```
. quietly estat elasticities if n_kids == 2, expenditure generate(ee)
```

. summarize ee*

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| ee_1 | 751 | .9028921 | .0753773 | .5095888 | 1.44884 |
| ee_2 | 751 | 1.087763 | .0664746 | .8448506 | 1.525114 |
| ee_3 | 751 | .9978958 | .1755427 | .7566877 | 5.07766 |
| ee_4 | 751 | .8523383 | .1053903 | .3864381 | 1.110392 |
| ee_5 | 751 | .9971274 | .082875 | .3257591 | 1.296199 |

The means of these variables match the point estimates in the previous estat elasticities output. The standard deviations reported here measure the spread of the individual observations' elasticities rather than the standard errors of the means as in the previous output.

A second way to compute elasticities is to first compute the means of the price variables, the expenditure variable, and any demographics and then compute the elasticity for this hypothetical household. To have estat elasticities do that, you use the atmeans option. Here we obtain the expenditure elasticities at the means for the subset of households with two children:
. estat elasticities if n_kids == 2, expenditure atmeans
Expenditure elasticities Number of obs $=751$

| Expenditure | Elasticity | Std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | $[95 \%$ conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | :---: | ---: |
| Dairy | .9155493 | .0232877 | 39.31 | 0.000 | .8699063 | .9611923 |
| Meats | 1.078329 | .0149179 | 72.28 | 0.000 | 1.04909 | 1.107567 |
| FruitVeg | .9804481 | .0201581 | 48.64 | 0.000 | .9409389 | 1.019957 |
| Flours | .8695964 | .0212882 | 40.85 | 0.000 | .8278722 | .9113206 |
| Misc | 1.004098 | .0246939 | 40.66 | 0.000 | .9556994 | 1.052498 |

Note: Elasticities are calculated at prices', demographic variables', and expenditure means.

With the atmeans option, we calculate the elasticities for a hypothetical household that may have, for example, 0.87 children and 1.93 adults. Without the atmeans option, we are calculating elasticities for households that do exist in the data, though taking the average of household elasticities poses its own conceptual issues.
Consider the following table:
Table 1. Average expenditure elasticities

| Consumer | $m$ | $E^{m}$ | $Q$ | $m^{\prime}$ | $Q^{\prime}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $A$ | 100 | 2 | 20 | 110 | 24 |
| $B$ | 200 | 1 | 30 | 220 | 33 |
| $C$ | 400 | 0.5 | 30 | 440 | 31.5 |
| Sum | 700 |  | 80 | 770 | 88.5 |
| Mean |  | 1.17 |  |  |  |

Column $m$ represents each consumer's initial total expenditure, $E^{m}$ is the consumer's expenditure elasticity for the good in question, and $Q$ is the quantity consumed. Column $m^{\prime}$ represents a $10 \%$ increase in each consumer's expenditure, and $Q^{\prime}$ represents the level of consumption based on the increases in total expenditure and the expenditure elasticities. The mean elasticity, analogous to what estat elasticities reports without the atmeans option, is 1.17 . However, based on the aggregate data, the expenditure elasticity works out to 1.06 .

So far in this example, we computed the expenditure elasticities for the subset of households with two children. We can also calculate the average elasticity for all households in our dataset under the counterfactual that all of them have two children. One way to do that is to type

```
. generate n_kids_backup = n_kids
. replace n_kids = 2
(3,409 real changes made)
. estat elasticities, expenditure
```

Expenditure elasticities $\quad$ Number of obs $=4,160$

| Expenditure | Elasticity | Std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | :---: | :---: |
| Dairy | .8464408 | .0266003 | 31.82 | 0.000 | .7943051 | .8985764 |
| Meats | 1.20188 | .0252998 | 47.51 | 0.000 | 1.152294 | 1.251467 |
| FruitVeg | 1.130297 | .0323216 | 34.97 | 0.000 | 1.066948 | 1.193646 |
| Flours | .7604338 | .0229378 | 33.15 | 0.000 | .7154766 | .8053911 |
| Misc | .9082412 | .0287833 | 31.55 | 0.000 | .8518269 | .9646554 |

```
. replace n_kids = n_kids_backup
(3,409 real changes made)
```

Here we first created a backup variable holding the true values of $n \_k i d s$, and then we set $n \_k i d s$ equal to two for all observations. After calling estat elasticities, we restored the true values.

## - Technical note

In principle, a second way to obtain the expenditure elasticities under the counterfactual that all households have two children would be to type

```
estat elasticities, expenditure at(n_kids=2)
```

The key is the at () option, which allows us to request that variables be set to the values we specify before calculating the elasticities. For more information about the at() option, see [R] margins, especially Syntax of at().

However, in this example, if you issue the previous command, you would obtain the error message

```
. estat elasticities, expenditure at(n_kids=2)
Option at() specified; using margins.
could not calculate numerical derivatives -- discontinuous region with missing
values encountered
r(459);
```

The issue is that for most demand systems the predicted quantities are nonlinear functions of prices. As the output indicates, when you specify the at() option, estat elasticities calls margins to obtain the desired results. Depending on the exact demand system and demographic specification, margins may not be able to obtain all the required derivatives numerically.

When you do not use the at() option, estat elasticities uses analytics formulas for the expenditure and price elasticities; Methods and formulas of [R] demandsys includes the elasticity formulas for all the demand systems implemented. Evaluating analytic formulas is quick, and most of the time is spent computing the variance-covariance matrix of the estimated mean elasticities, because that does use numerical derivatives. Because those derivatives are for a sample mean, rather than individual observations, you are unlikely to obtain the same message as margins issued in the previous command.

In contrast, margins uses numerical derivatives for all its calculations, and, moreover, it must incur the added expense of having to call predict to evaluate predicted quantities. One case where you would need to use margins is to obtain, say, a quantity elasticity with respect to a change in a demographic variable, because those elasticities are not programmed into demandsys.

In the text after example 4 and in example 6 of $[R]$ demandsys, we cautioned that after fitting a generalized model that allows for subsistence or committed quantities, you should check whether that interpretation actually holds. If for some household $\sum_{g} p_{g}\left(\mu_{g}+\boldsymbol{\nu}_{g}^{\prime} \mathbf{d}\right)>m$, then either the household is not consuming enough to meet what we think is a minimum subsistence or our assumption that this quantity represents a minimum subsistence is wrong. Moreover, if $\mu_{g}+\boldsymbol{\nu}_{g}^{\prime} \mathbf{d}<0$, then we are saying that the minimum required level of $g$ is less than 0 , which implies that good $g$ is in fact not needed for subsistence.

## > Example 2

This example is a continuation of example 6 in [R] demandsys. In that example, we fit a generalized QUAIDS model, which we refit here:

```
. use https://www.stata-press.com/data/r18/food_consumption, clear
(Food consumption)
. demandsys gquaids w_dairy w_proteins w_fruitveg w_flours w_misc,
> prices(p_dairy p_proteins p_fruitveg p_flours p_misc)
> demographics(n_kids n_adults) piconstant(3) expenditure(expfd) nolog
    (output omitted)
```

Next, we compute variables containing each household's implied minimum quantity of each good conditional on that household's demographics. Given those variables, we can then calculate the expenditure needed to acquire the minimum quantities given the prices each household faces. We type

```
. estat parameters
. return list
macros:
                r(names) : "alpha beta Gamma lambda mu Nu"
matrices:
            r(Nu) : 5 x 2
            r(mu) : 5 x 1
            r(lambda) : 5 x 1
                        r(Gamma) : 5 x 5
                        r(beta) : 5 x 1
                            r(alpha) : 5 x 1
. matrix mu = r(mu)
. matrix Nu = r(Nu)
. forvalues g = 1/5 {
    2. generate minq_'g' = mu['g', 1] + Nu['g',1]*n_kids + Nu['g',2]*n_adults
    3. }
. generate sub_exp = p_dairy*minq_1 + p_proteins*minq_2
> + p_fruitveg*minq_3 + p_flour*minq_4 + p_misc*minq_5
```

We first issued the command estat parameters to obtain the estimated parameter matrices from our demand system. The following command shows that six vectors and matrices were stored, following the layout of the coefficient table from demandsys. To compute minimum quantities, we need matrices $\boldsymbol{\mu}$ and $\mathbf{N}$, so we transferred those $r()$ results to Stata matrices.

Because we specified n_kids first in the demographics() option of demandsys, that variable's coefficients are stored in the first column of our matrix $\mathrm{r}(\mathrm{Nu})$, which we converted to Nu . The second column corresponds to coefficients associated with n_adults. We looped over the five goods in our system and created variables named minq- $g$ containing the minimum quantities. The final generate statement calculates the minimum expenditure for each household given the prices it faced and our calculated minimum quantities.

Now we can look at the results.

| . summarize minq_* |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| Variable | Obs | Mean | Std. dev. | Min | Max |
| minq_1 | 4,160 | -1.604524 | .9955551 | -7.287278 | -.2078816 |
| minq_2 | 4,160 | -2.893996 | 1.743902 | -13.71866 | -.6731596 |
| minq_3 | 4,160 | -5.344703 | 3.802853 | -29.30052 | -.5518757 |
| minq_4 | 4,160 | .3094949 | .1354879 | -.0171549 | 1.328885 |
| minq_5 | 4,160 | -.1878336 | .2030023 | -1.34631 | .0894621 |

For the first three goods in our system, the calculated minimum quantity is negative for every single household in our sample. That is hardly encouraging if we wish to take the subsistence interpretation seriously, because it implies three of the five categories of food we have are not required for subsistence. Moreover, on average, good 5 is not required either. Even for good 4, for some households, the minimum quantity is negative. Finally, we look at the expenditure needed to purchase the minimum quantities of the five goods:

| • summarize sub_exp |  |  |  |  |  |
| ---: | :---: | :---: | :---: | :---: | ---: |
| Variable | Obs | Mean | Std. dev. | Min | Max |
| sub_exp | 4,160 | -8.10118 | 5.480523 | -43.8327 | .2678578 |

Not surprisingly given the previous summary statistics, the minimum required expenditure for most households is less than zero.

What are we to make of the results in the previous example? We think there are at least four explanations:

1. There are minimum quantities of each good consumers must purchase for subsistence, but our demand system is misspecified. If you believe this to be true, you might try changing the demographic variables for which you control. Alternatively, try a different model; for example, use a generalized QUAIDS model rather than a generalized translog or AIDS model.
2. The data are simply not compatible with a minimum subsistence interpretation. That does not imply the results of the fitted demand system must be ignored. As Pollak and Wales (1992, 75) write, any demand system that includes demographic translation should include a constant term in the demand equations-which is the key characteristic of the models we refer to as "generalized". For example, rather than using the translog model with demographic translation, you should instead use the generalized translog model with demographic translation. In other words, the $\mu$ parameters do belong in the model, but they should not be construed as minimum quantities required for subsistence.
3. Items for which the calculated minimum quantities are positive for all observations must be purchased to achieve subsistence, but items for which the minimum quantities are negative need not be consumed for subsistence. Under this interpretation, in our example, households must consume breads, cereals, and pastas but need not consume any other foods for minimal subsistence. That is not particularly palatable to us.
4. The procedure we used is useful as a diagnostic tool, but it is not a formal statistical test. Our estimated parameters are subject to sampling variation, and therefore our calculated minimum quantities are also subject to sampling variation. We have not accounted for this. If we were to conduct a test of the hypothesis that all minimum quantities are zero or more versus the alternative that some are negative, we may not be able to reject the null hypothesis.

## Evaluating elasticities

The elasticities that are reported with estat elasticities refer to the slope of the fitted demand curve. Let us explain what we mean. Look at figure 1 . We have plotted a fitted demand curve $D^{\mathrm{F}}$ as a straight line for simplicity, and the large dots represent observed (price, quantity) pairs for two observations. The dotted lines represent each observation's residual, and the plus signs represent the predicted quantities given the two observations' prices. While quantity is a function of price here, following the influential English economist Alfred Marshall, we plot price on the ordinate; hence, the lines connecting observations to the regression line are horizontal, not vertical.

Figure 1. Actual and predicted quantities
For the AIDS model without demographic variables included, we can show that the expenditure elasticity for the $g$ th good is given by

$$
E^{g}=1+\frac{\beta_{g}}{w_{g}}
$$

We do not observe the true value $\beta_{g}$, so to compute the elasticity for household $i$, we have no choice but to use the estimated $\widehat{\beta}_{g}$. However, we observe both household $i$ 's true expenditure share $w_{g i}$, and we can compute its predicted expenditure share $\widehat{w_{g i}}$.

In terms of figure 1, the issue is whether we evaluate the expenditure or any other elasticity formula at the red and blue dots or at their corresponding fitted values shown by the pluses on the demand curve. We believe the correct procedure is to evaluate elasticity formulas at their fitted values. That is, estat elasticities evaluates the expenditure share elasticity for household $i$ as

$$
\widehat{E_{i}^{g}}=1+\frac{\widehat{\beta_{g}}}{\widehat{w_{g i}}}
$$

After all, for policy or other analyses, what we want to know is essentially the slope of the fitted demand curve. We need to be able to predict the effect of a policy on a household, and in general to do that, we predict the household's response with the policy imposed and compare it with the predicted response in the absence of the policy. In other words, our elasticity computations measure the slope of the fitted demand curve, not the slope of an imaginary line that passes through one of our dots that may or may not be parallel to the fitted demand curve.

In contrast, the postestimation tools accompanying the community-contributed quaids command of Poi (2012) use the actual values $w_{g}$ to calculate elasticities. Thus, users of that command will see
minor differences when refitting models using demandsys and estat elasticities. We believe, however, that evaluating the formulas at the predicted expenditure shares, or equivalently, evaluating the elasticity formulas along the demand curve rather than at points in space that need not lie on the demand curve, is conceptually more sound. Moreover, the elasticity results reported after quaids cannot be replicated using the margins command, but the results reported by estat elasticities are identical to those one would obtain using margins.

## Compensating and equivalent variation

Although students in introductory economics courses learn of consumer's surplus as a way to measure whether consumers are better or worse off in response to a policy such as a tax, it has limitations. Perhaps most importantly, consumer's surplus is not well defined in most cases; see Auerbach (1985). Also see Harberger (1964), who develops a method for calculating consumer welfare when multiple prices change but assumes the timing of the price changes is scattered rather than occurring simultaneously. Hines (1999) provides a historical overview of consumer's welfare measurement.

The workhorse metrics used to evaluate a policy are compensating and equivalent variation (CV and EV, respectively). These metrics assign a monetary amount to a household's change in welfare and can accommodate policies that cause multiple prices to change simultaneously. Because predict after demandsys allows us to obtain the predicted values of the expenditure and indirect utility functions, these metrics are easy to obtain.

CV measures how much a social planner would have to compensate a consumer to offset the effect of, say, a tax that causes prices to rise. Consider figure 2, which illustrates CV for two goods and would be familiar to those who have studied intermediate microeconomics.

Figure 2. CV if the price of good 1 rises
Initially, the price of good 1 is $p_{0}$, and the line segment $\overline{A \cdot p_{0} / m}$ represents the budget constraint. The consumer purchases $q_{0}$ units of good 1 and enjoys utility level $U_{0}$. Now suppose the price of good 1 rises to $p_{1}$ : consumption of good 1 falls to $q_{1}$ and utility falls to $U_{1}$; line segment $\overline{A \cdot p_{1} / m}$ represents the new budget constraint.

The dotted line segment $\overline{B \cdot p_{1}^{\prime} m}$ represents a budget constraint based on price $p_{1}$ but shifted outward so that the consumer can still achieve utility level $U_{0}$ when facing price $p_{1}$, by consuming $q_{1}^{\prime}$. The line segment $\overline{B \cdot A}$ represents the CV . It tells us, in the face of a higher price for good 1 , how much the social planner would have to compensate this consumer so that he or she can enjoy
the same level of utility as before the price increase. In this case, CV is negative because the social planner must pay the consumer.

Notice the close similarity to the concept of the income and substitution effects that cause demand curves to slope downward. CV, and EV as we will see shortly, is a measure of the income effect.

Mathematically, CV is defined as

$$
\begin{aligned}
\mathbf{C V} & =e\left(\mathbf{p}^{1}, u^{1}\right)-e\left(\mathbf{p}^{1}, u^{0}\right) \\
& =e\left(\mathbf{p}^{0}, u^{0}\right)-e\left(\mathbf{p}^{1}, u^{0}\right) \\
& =m-e\left(\mathbf{p}^{1}, u^{0}\right)
\end{aligned}
$$

where $\mathbf{p}^{0}$ and $\mathbf{p}^{1}$ are the price vectors before and after the policy is implemented and $u^{0}$ is the household's initial level of utility. Where do we get that level of utility, considering that utility is unobserved? The answer is the indirect utility function, which expresses utility as a function of observed prices and expenditure; we can evaluate the indirect utility function by calling predict with the iuf option. With the indirect utility variable in hand, we then call predict with the ef option and set the price variables to $\mathbf{p}^{1}$.

## > Example 3

We compute household CV in response to a $10 \%$ increase in the price of dairy products, holding all other prices constant. See Poi (2002) for similar computations for an expanded look at the welfare implications of lower dairy and other prices. First, we fit a generalized QUAIDS model controlling for the number of children and adults in each household. We type

```
. use https://www.stata-press.com/data/r18/food_consumption, clear
(Food consumption)
. quietly demandsys gquaids w_dairy w_proteins w_fruitveg w_flours w_misc,
> prices(p_dairy p_proteins p_fruitveg p_flours p_misc)
> expenditures(expfd) demographics(n_kids n_adults) nolog
. estimates store gquaids
```

We stored our estimation results for later use by specifying the estimates store command. Next, we obtain each household's initial utility $u^{0}$ by evaluating the indirect utility function:

```
. predict u0, iuf
```

Now, we create a new dairy price variable containing the price each household will face after the imposition of the tax. Given that price variable and initial utility $u^{0}$, we can calculate each household's new level of expenditure. Finally, we compute the CV. We type

```
. generate ptax_dairy = p_dairy * 1.10
. predict ep1u0, ef utilities(u0)
> prices(ptax_dairy p_proteins p_fruitveg p_flours p_misc)
. generate cv = expfd - ep1u0
```

Here we used the prices () option of predict to specify the new prices $\mathbf{p}^{1}$ at which we want the expenditure function. Had we not specified that option, predict would have used the prices used at estimation, $\mathbf{p}^{0}$. Because we wanted to evaluate the function at the level of expenditures $m$, the same as used at estimation, we did not need to specify the expenditures () option of predict.

We summarize our results by looking at the average CV by household size:
. mean cv, over(n_kids)
Mean estimation

|  |  |  | Number of obs $=4,160$ |  |
| :---: | ---: | ---: | ---: | ---: |
| c.cv@n_kids |  |  |  |  |
| 0 | -.5142129 | .0066562 | -.5272626 | -.5011631 |
| 1 | -.7762653 | .013486 | -.802705 | -.7498257 |
| 2 | -.9060989 | .014986 | -.9354795 | -.8767183 |
| 3 | -1.067159 | .0268302 | -1.11976 | -1.014557 |
| 4 | -1.22238 | .0506472 | -1.321675 | -1.123084 |
| 5 | -1.550712 | .158197 | -1.860863 | -1.240561 |
| 6 | -1.304841 | .2223387 | -1.740744 | -.8689384 |
| 7 | -1.902748 | .1828158 | -2.261165 | -1.544331 |
| 8 | -2.923615 | . | . | . |
| 10 | -1.743889 | . | . | . |

The standard errors of the means are missing for households with 8 and 10 children because only one household of each size exists in our data. For the most part, CV becomes more negative with the number of children, as we expected, because larger households are likely to consume more dairy products by virtue of there being more people within the household. To reiterate, CV is negative here, indicating that the social planner must transfer money to the consumer. For a price decrease, CV would be positive.

EV is similar to CV, except that we use the postpolicy level of utility and the initial price vector rather than the initial level of utility and postpolicy price vector. We have

$$
\begin{aligned}
\mathrm{EV} & =e\left(\mathbf{p}^{0}, u^{1}\right)-e\left(\mathbf{p}^{0}, u^{0}\right) \\
& =e\left(\mathbf{p}^{0}, u^{1}\right)-e\left(\mathbf{p}^{1}, u^{1}\right) \\
& =e\left(\mathbf{p}^{0}, u^{1}\right)-m
\end{aligned}
$$

To aid in understanding EV, you may wish to sketch a diagram similar to figure 2. EV tells us how much consumers would be willing to pay to trade at the original price vector rather than the postpolicy one. In other words, EV tells us the change in expenditure that would yield $u^{1}$ if total expenditure were to change rather than the price vector. A negative value indicates that consumers are worse off.

## > Example 4

Continuing the previous example, to calculate EV, we first need to calculate the new level of utility $u^{1}$ each household will enjoy based on the postpolicy dairy price. Because the preferences underlying all the demand systems implemented by demandsys are locally nonsatiated, each household will exhaust its full budget. Thus, the level of expenditure we supply as an argument to the indirect utility function is simply $m$, the value we used during estimation. To get $u^{1}$, we can therefore call predict, iuf at postpolicy prices.

```
. estimates restore gquaids
(results gquaids are active now)
. predict u1, iuf prices(ptax_dairy p_proteins p_fruitveg p_flours p_misc)
```

We had to restore our estimation results because the means command we used previously overwrites results in e ().

Now we evaluate the expenditure function at original prices and our computed level of utility $u^{1}$. Because the original prices were used at estimation, we do not need to supply alternative prices via the prices() option. We type

```
. predict epOu1, ef utilities(u1)
```

We are now ready to compute EV and summarize the results:

```
. generate ev = ep0u1 - expfd
. mean ev, over(n_kids)
```

Mean estimation $\quad$ Number of obs $=4,160$

|  | Mean | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: |
| c.ev@n_kids |  |  |  |  |
| 0 | -.5073723 | .0065622 | -.5202378 | -.4945068 |
| 1 | -.7660214 | .013292 | -.7920807 | -.739962 |
| 2 | -.8940226 | .014762 | -.922964 | -.8650811 |
| 3 | -1.052524 | .0264206 | -1.104322 | -1.000725 |
| 4 | -1.205508 | .0498826 | -1.303304 | -1.107711 |
| 5 | -1.528722 | .1554489 | -1.833485 | -1.223959 |
| 6 | -1.285955 | .218652 | -1.71463 | -.8572807 |
| 7 | -1.871663 | .178062 | -2.22076 | -1.522567 |
| 8 | -2.87738 | . | . | . |
| 10 | -1.716629 | . | . | . |

For small price changes, CV and EV will be similar; however, they will not match because CV is based on the original level of utility and postpolicy prices and EV is based on the postpolicy level of utility and original prices. Which one is more appropriate in any situation depends on the policy and goals. If the government is implementing, say, a carbon tax to reduce consumption of goods and services that emit carbon dioxide, CV may be a better choice because it tells how much the government must compensate consumers so that their overall utilities do not change. If one is evaluating the introduction of a new product competing with an existing product into the market, EV may be a better metric because it could be interpreted as a measure of how much better off consumers would be thanks to lower prices.

As with our analysis of estimated minimum quantities in example 2, here we have not attempted to obtain measures of the sampling variation associated with the CV or EV. One alternative to obtain, say, the sampling variation of the mean CV across households would be to use the bootstrap, being sure to bootstrap the entire procedure, including refitting the model at each bootstrap replication as well as obtaining the desired statistics.

## Options for symplot, quantile, and qqplot

$\qquad$ Plot
marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.
marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options.
$\qquad$ Reference line
rlopts(cline_options) affect the rendition of the reference line; see [G-3] cline_options.
addplot (plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

Y axis, X axis, Titles, Legend, Overall
twoway_options are any of the options documented in [G-3] twoway_options, excluding by (). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

## Options for qnorm and pnorm

$\qquad$ Main
grid adds grid lines at the $0.05,0.10,0.25,0.50,0.75,0.90$, and 0.95 quantiles when specified with qnorm. With pnorm, grid is equivalent to yline(.25,.5,.75) xline(.25, .5, .75).

## $\sqrt{\text { Plot }}$

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.
marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options.

rlopts (cline_options) affect the rendition of the reference line; see [G-3] cline_options.

```
            Add plots
    addplot (plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.
```

$\longleftarrow \sqrt{\mathrm{Y} \text { axis, } \mathrm{X} \text { axis, Titles, Legend, Overall }}$
twoway_options are any of the options documented in [G-3] twoway_options, excluding by (). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

## Options for qchi and pchi

$\qquad$ Main
grid adds grid lines at the $0.05,0.10,0.25,0.50,0.75,0.90$, and .95 quantiles when specified with qchi. With pchi, grid is equivalent to yline (. $25, .5, .75$ ) xline (. $25, .5, .75$ ). $\mathrm{df}(\#)$ specifies the degrees of freedom of the $\chi^{2}$ distribution. The default is $\mathrm{df}(1)$.
$\qquad$ $\sqrt{\text { Plot }}$
marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.
marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options.

Reference line
rlopts(cline_options) affect the rendition of the reference line; see [G-3] cline_options.

Add plots
addplot (plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

Y axis, X axis, Titles, Legend, Overall
twoway_options are any of the options documented in [G-3] twoway_options, excluding by (). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

## Remarks and examples

Remarks are presented under the following headings:

```
symplot
quantile
qqplot
qnorm
pnorm
qchi
pchi
```

## symplot

$\rangle$ Example 1
We have data on 74 automobiles. To make a symmetry plot of the variable price, we type

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. symplot price
```

All points would lie along the reference line (defined as $y=x$ ) if car prices were symmetrically distributed. The points in this plot lie above the reference line, indicating that the distribution of car prices is skewed to the right - the most expensive cars are far more expensive than the least expensive cars are inexpensive.

The logic works as follows: a variable, $z$, is distributed symmetrically if

$$
\text { median }-z_{(i)}=z_{(N+1-i)}-\text { median }
$$

where $z_{(i)}$ indicates the $i$ th-order statistic of $z$. symplot graphs $y_{i}=$ median $-z_{(i)}$ versus $x_{i}=$ $z_{(N+1-i)}$ - median.

For instance, consider the largest and smallest values of price in the example above. The most expensive car costs $\$ 15,906$ and the least expensive, $\$ 3,291$. Let's compare these two cars with the typical car in the data and see how much more it costs to buy the most expensive car, and compare that with how much less it costs to buy the least expensive car. If the automobile price distribution is symmetric, the price differences would be the same.

Before we can make this comparison, we must agree on a definition for the word "typical". Let's agree that "typical" means median. The price of the median car is $\$ 5,006.50$, so the most expensive car costs $\$ 10,899.50$ more than the median car, and the least expensive car costs $\$ 1,715.50$ less than the median car. We now have one piece of evidence that the car price distribution is not symmetric. We can repeat the experiment for the second-most-expensive car and the second-least-expensive car. We find that the second-most-expensive car costs $\$ 9,494.50$ more than the median car, and the second-least-expensive car costs $\$ 1,707.50$ less than the median car. We now have more evidence. We can continue doing this with the third most expensive and the third least expensive, and so on.

Once we have all of these numbers, we want to compare each pair and ask how similar, on average, they are. The easiest way to do that is to plot all the pairs.

## quantile

> Example 2
We have data on the prices of 74 automobiles. To make a quantile plot of price, we type

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. quantile price, rlopts(clpattern(dash)) ytitle(Quantiles of price)
```

We changed the pattern of the reference line by specifying rlopts(clpattern(dash)).
In a quantile plot, each value of the variable is plotted against the fraction of the data that have values less than that fraction. The diagonal line is a reference line. If automobile prices were rectangularly distributed, all the data would be plotted along the line. Because all the points are below the reference line, we know that the price distribution is skewed right.

## qqplot

> Example 3
We have data on the weight and country of manufacture of 74 automobiles. We wish to compare the distributions of weights for domestic and foreign automobiles:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. generate weightd=weight if !foreign
(22 missing values generated)
. generate weightf=weight if foreign
(52 missing values generated)
. qqplot weightd weightf
```

## qnorm

## > Example 4

Continuing with our price data on 74 automobiles, we now wish to compare the distribution of price with the normal distribution:
. qnorm price, grid

Grid lines are $5,10,25,50,75,90$, and 95 percentiles.
The result shows that the distributions are different.

## - Technical note

The idea behind qnorm is recommended strongly by Miller (1997): he calls it probit plotting. His recommendations from much practical experience should interest many users. "My recommendation for detecting nonnormality is probit plotting" (Miller 1997, 10). "If a deviation from normality cannot be spotted by eye on probit paper, it is not worth worrying about. I never use the Kolmogorov-Smirnov test (or one of its cousins) or the $\chi^{2}$ test as a preliminary test of normality. They do not tell you how the sample is differing from normality, and I have a feeling they are more likely to detect irregularities in the middle of the distribution than in the tails" (Miller 1997, 13-14).

## pnorm

## Example 5

Quantile-normal plots emphasize the tails of the distribution. Normal probability plots put the focus on the center of the distribution:
. pnorm price, grid

## qchi

## > Example 6

Suppose that we want to examine the distribution of the sum of squares of price and mpg, standardized for their variances.
. egen $c 1=$ std(price)
. egen $c 2=\operatorname{std}(m p g)$
. generate ch = c1^2 + c2~2
. qchi ch, df(2) grid ylabel(, axis(2) labsize(*.8) format(\%4.2f))
> xlabel(, axis(2) format(\%4.2f))

The quadratic form is clearly not $\chi^{2}$ with 2 degrees of freedom.

## pchi

## > Example 7

We can focus on the center of the distribution by doing a probability plot:
. pchi ch, df(2) grid

## Methods and formulas

Let $x_{(1)}, x_{(2)}, \ldots, x_{(N)}$ be the data sorted in ascending order.
If a continuous variable, $x$, has a cumulative distribution function $F(x)=P(X \leq x)=p$, the quantiles $x_{p_{i}}$ are such that $F\left(x_{p_{i}}\right)=p_{i}$. For example, if $p_{i}=0.5$, then $x_{0.5}$ is the median. When we plot data, the probabilities, $p_{i}$, are often referred to as plotting positions. There are many different conventions for choice of plotting positions, given $x_{(1)} \leq \cdots \leq x_{(N)}$. Most belong to the family $(i-a) /(N-2 a+1) . a=0.5$ (suggested by Hazen) and $a=0$ (suggested by Weibull) are popular choices.

For a wider discussion of the calculation of plotting positions, see Cox (2002).
symplot plots median $-x_{(i)}$ versus $x_{(N+1-i)}$ - median.
quantile plots $x_{(i)}$ versus $(i-0.5) / N$ (the Hazen position).
qnorm plots $x_{(i)}$ against $q_{i} \times \widehat{\sigma}+\widehat{\mu}$, where $q_{i}=\Phi^{-1}\left(p_{i}\right), \Phi$ is the cumulative normal distribution, $p_{i}=i /(N+1)$ (the Weibull position), $\widehat{\sigma}$ is the standard deviation, and $\widehat{\mu}$ is the mean of the data.
pnorm plots $\Phi\left\{\left(x_{i}-\widehat{\mu}\right) / \widehat{\sigma}\right\}$ versus $p_{i}=i /(N+1)$, where $\widehat{\mu}$ is the mean of the data and $\widehat{\sigma}$ is the standard deviation.
qchi and pchi are similar to qnorm and pnorm; the cumulative $\chi^{2}$ distribution is used in place of the cumulative normal distribution.
qqplot is just a two-way scatterplot of one variable against the other after both variables have been sorted into ascending order, and both variables have the same number of nonmissing observations. If the variables have unequal numbers of nonmissing observations, interpolated values of the variable with more data are plotted against the variable with fewer data.

Ramanathan Gnanadesikan (1932-2015) was born in Madras. He obtained degrees from the Universities of Madras and North Carolina. He worked in industry at Procter \& Gamble, Bell Labs, and Bellcore, as well as in universities, retiring from Rutgers in 1998. Among many contributions to statistics, he is especially well known for work on probability plotting, robustness, outlier detection, clustering, classification, and pattern recognition.
Martin Bradbury Wilk (1922-2013) was born in Montreal. He obtained degrees in chemical engineering and statistics from McGill and Iowa State Universities. After holding several statisticsrelated posts in industry and at universities (including periods at Princeton, Bell Labs, and Rutgers), Wilk was appointed Chief Statistician at Statistics Canada (1980-1986). He is especially well known for his work with Gnanadesikan on probability plotting and with Shapiro on tests for normality.

## Acknowledgments

We thank Peter A. Lachenbruch (1937-2021), Emeritus Appointment, Biostatistics, College of Public Health and Human Sciences, Oregon State University for writing the original versions of qchi and pchi. Patrick Royston of the MrC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model also published a similar command in Royston (1996).

## Title

display - Substitute for a hand calculator

Description Quick start Syntax Remarks and examples Also see

## Description

display displays strings and values of scalar expressions.
display really has many more features and a more complex syntax diagram, but the diagram shown above is adequate for interactive use. For a full discussion of display's capabilities, see [P] display.

## Quick start

Perform calculations interactively
display $100 * 100$
Same as above, but include comma in the result
display \%6.Ofc 100*100
Verify choice of datetime function
display \%tm monthly("January 1983", "MY")
View formatted mean after summarize
display $\% 5.2 \mathrm{fr}$ (mean)
Add the variance with a different format on its own line

```
display "mean = " %5.2f r(mean) _newline "variance = " %10.4f r(Var)
```

## Syntax

display exp

## Remarks and examples

display can be used as a substitute for a hand calculator.

## $>$ Example 1

display $2+2$ produces the output 4. Stata variables may also appear in the expression, such as in display myvar/2. Because display works only with scalars, the resulting calculation is performed only for the first observation. You could type display myvar[10]/2 to display the calculation for the 10th observation. Here are more examples:

```
. display sqrt(2)/2
.70710678
. display normal(-1.1)
. }1356660
. di (57.2-3)/(12-2)
5.42
    display myvar/10
7
. display myvar[10]/2
3.5
```

## Title

do - Execute commands from a file

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Option | Reference | Also see |  |

## Description

do and run cause Stata to execute the commands stored in filename just as if they were entered from the keyboard. do echoes the commands as it executes them, whereas run is silent.

## Quick start

Execute commands stored in myfile.do
do myfile

Same as above, passing first arg in local macro 1 and arg2 in local macro 2 for use by myfile. do do myfile "first arg" arg2

Execute commands stored in myfile.do, continuing execution even if an error occurs in one or more commands
do myfile, nostop
Execute commands stored in myfile.do silently
run myfile

## Menu

File > Do...

## Syntax

$\{\mathrm{do} \mid \underline{\text { run }}\}$ filename $[$ arguments $][$, nostop $]$
filename (called a do-file) can be created using Stata's Do-file Editor; see [R] doedit. This file will be a standard text file. filename can also be created by using a non-Stata text editor; see [D] shell for a way to invoke your favorite editor from inside Stata. Ensure that you save the file in ASCII or UTF-8 format.

If filename is specified without an extension, .do is assumed.
If the path or filename contains spaces, it should be enclosed in double quotes.
A complete discussion of do-files, including information on arguments, can be found in [U] 16 Do-files.

## Option

nostop allows the do-file to continue executing even if an error occurs. Normally, Stata stops executing the do-file when it detects an error (nonzero return code).

## Reference

Jenkins, S. P. 2006. Stata tip 32: Do not stop. Stata Journal 6: 281.

## Title

doedit - Edit do-files and other text files
Description Quick start Menu Syntax Remarks and examples
Also see

## Description

doedit opens the Do-file Editor. This text editor lets you create and edit do-files, which typically contain a series of Stata commands. If you specify filename, doedit will open a text file, such as a do-file or an ado-file, saved to disk.

## Quick start

Open a new untitled do-file in the Do-file Editor
doedit
Open new or existing do-file myfile.do in the Do-file Editor
doedit myfile

## Menu

Window > Do-file Editor

## Syntax

doedit [filename]

## Remarks and examples

Clicking on the Do-file Editor button is equivalent to typing doedit.
doedit, typed by itself, invokes the Editor with an empty document. If you specify filename, that file is displayed in the Editor.

You may have more than one Do-file Editor open at once. Each time you submit the doedit command, a new window will be opened.

A tutorial discussion of doedit can be found in the Getting Started with Stata manual. Read [U] 16 Do-files for an explanation of do-files, and then read [GSW] 13 Using the Do-file Editorautomating Stata to learn how to use the Do-file Editor to create and execute do-files.

## Title

dotplot - Comparative distribution dotplots

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Acknowledgments |
| Reference |  |  |  |

## Description

A dotplot is a scatterplot with values grouped together vertically ("binning", as in a histogram) and with plotted points separated horizontally. The aim is to display all the data for several variables or groups in one compact graphic.

## Quick start

Dotplot of v1

```
dotplot v1
```

Columns with separate dotplots of v 1 for each level of categorical variable a dotplot v1, over(a)

Same as above, but with the dots centered in each column
dotplot v1, over(a) center
Dotplots for v1, v2, and v3 in separate columns
dotplot v1 v2 v3
Add a horizontal line of pluses at the mean of each variable dotplot v1 v2 v3, mean

Add pluses for the medians and dashed lines for the upper and lower quartiles dotplot v1 v2 v3, median bar

## Menu

Graphics $>$ Distributional graphs $>$ Distribution dotplot

## Syntax

Dotplot of varname, with one column per value of groupvar
dotplot varname [if] [in] [, options]

Dotplot for each variable in varlist, with one column per variable

```
dotplot varlist [if] [in] [, options]
```

options

## Options

over(groupvar)
nx (\#)
ny (\#)
incr (\#)
mean median
bounded
bar
nogroup
center
Plot
marker_options
marker_label_options
Y axis, X axis, Titles, Legend, Overall
twoway_options
display one columnar dotplot for each value of groupvar
horizontal dot density; default is $\mathrm{nx}(0)$
vertical dot density; default is ny (35)
label every \# group; default is incr (1)
plot a horizontal line of pluses at the mean or median use minimum and maximum as boundaries
plot horizontal dashed lines at shoulders of each group
use the actual values of yvar
center the dot for each column
change look of markers (color, size, etc.)
add marker labels; change look or position
any options other than by () documented in [G-3] twoway_options
collect is allowed; see [U] 11.1.10 Prefix commands.

## Options

Options
over (groupvar) identifies the variable for which dotplot will display one columnar dotplot for each value of groupvar. over() may not be specified in the second syntax.
nx (\#) sets the horizontal dot density. A larger value of \# will increase the dot density, reducing the horizontal separation between dots. This option will increase the separation between columns if two or more groups or variables are used.
ny (\#) sets the vertical dot density (number of "bins" on the $y$ axis). A larger value of \# will result in more bins and a plot that is less spread out horizontally. \# should be determined in conjunction with nx() to give the most pleasing appearance.
incr(\#) specifies how the $x$ axis is to be labeled. incr (1), the default, labels all groups. incr (2) labels every second group.
[mean $\mid$ median] plots a horizontal line of pluses at the mean or median of each group.
bounded forces the minimum and maximum of the variable to be used as boundaries of the smallest and largest bins. It should be used with one variable whose support is not the whole of the real line and whose density does not tend to zero at the ends of its support, for example, a uniform random variable or an exponential random variable.
bar plots horizontal dashed lines at the "shoulders" of each group. The shoulders are taken to be the upper and lower quartiles unless mean has been specified; here they will be the mean plus or minus the standard deviation.
nogroup uses the actual values of yvar rather than grouping them (the default). This option may be useful if yvar takes on only a few values.
center centers the dots for each column on a hidden vertical line.
$\qquad$ Plot
marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.
marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options. marker_label_options are not allowed if varlist is specified.

Y axis, X axis, Titles, Legend, Overall
twoway_options are any of the options documented in [G-3] twoway_options, excluding by (). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

## Remarks and examples

dotplot produces a figure that has elements of a boxplot, a histogram, and a scatterplot. Like a boxplot, it is most useful for comparing the distributions of several variables or the distribution of 1 variable in several groups. Like a histogram, the figure provides a crude estimate of the density, and, as with a scatterplot, each symbol (dot) represents 1 observation.

## > Example 1

dotplot may be used as an alternative to Stata's histogram graph for displaying the distribution of one variable.
. set seed 123456789
. set obs 1000
. generate norm = rnormal()
. dotplot norm, title("Normal distribution, sample size 1000")
Normal distribution, sample size 1000

## Example 2

The over () option lets us use dotplot to compare the distribution of one variable within different levels of a grouping variable. The center, median, and bar options create a graph that may be compared with Stata's boxplot; see [G-2] graph box. The next graph illustrates this option with Stata's automobile dataset.

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. dotplot mpg, over(foreign) nx(25) ny(10) center median bar
```

## > Example 3

The second version of dotplot lets us compare the distribution of several variables. In the next graph, all 10 variables contain measurements on tumor volume.

```
. use https://www.stata-press.com/data/r18/dotgr
. dotplot g1r1-g1r10, ytitle("Tumor volume, cu mm")
```

## Example 4

When using the first form with the over () option, we can encode a third dimension in a dotplot by using a different plotting symbol for different groups. The third dimension cannot be encoded with a varlist. The example is of a hypothetical matched case-control study. The next graph shows the exposure of each individual in each matched stratum. Cases are marked by the letter ' $x$ ', and controls are marked by the letter ' $o$ '.

```
. use https://www.stata-press.com/data/r18/dotdose
. label define symbol 0 "o" 1 "x"
. label values case symbol
```

```
dotplot dose, over(strata) m(none) mlabel(case) mlabp(0) center
```

> Example 5
dotplot can also be used with two virtually continuous variables as an alternative to jittering the data to distinguish ties. We must use the xlabel() option, because otherwise dotplot will attempt to label too many points on the $x$ axis. It is often useful in such instances to use a value of nx that is smaller than the default. That was not necessary in this example, partly because of our choice of symbols.

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. generate byte hi_price = (price>10000) if price < .
. label define symbol 0 "|" 1 "o"
. label values hi_price symbol
. dotplot weight, over(gear_ratio) m(none) mlabel(hi_price) mlabp(0) center
> xlabel(#5)
```

## > Example 6

The following figure is included mostly for aesthetic reasons. It also demonstrates dotplot's ability to cope with even very large datasets. The sample size for each variable is 10,000 , so it may take a long time to print.

```
. clear all
. set seed 123456789
. set obs }1000
. generate norm0 = rnormal()
. generate norm1 = rnormal() + 1
. generate norm2 = rnormal() + 2
. label variable norm0 "N(0,1)"
. label variable norm1 "N(1,1)"
. label variable norm2 "N(2,1)"
. dotplot norm0 norm1 norm2
```

## Stored results

dotplot stores the following in $r()$ :
Scalars
$r(n x) \quad$ horizontal dot density
$r(n y) \quad$ vertical dot density

## Acknowledgments

dotplot was written by Peter Sasieni of the King's Clinical Trials Unit at King's College London, and Patrick Royston of the MrC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model.

## Reference

## Title

dstdize - Direct and indirect standardization

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options for dstdize | Options for istdize | Remarks and examples | Stored results |
| Methods and formulas | Acknowledgments | References | Also see |

## Description

dstdize produces standardized rates, a weighted average of the stratum-specific rates.
istdize produces indirectly standardized rates that are appropriate when the stratum-specific rates for the population being studied are either unavailable or unreliable.
istdize also calculates a point estimate and exact confidence interval for the study population's standardized mortality ratio (SMR) or the standardized incidence ratio (SIR).

## Quick start

## Direct standardization

Use reference population saved in mypop.dta to standardize v 1 with stratum identifier svar and stratum size v2 for catvar dstdize v1 v2 svar, by (catvar) using(mypop)

Same as above, but with reference population in memory where catvar $=1$ dstdize v1 v2 svar, by (catvar) base(1)

Same as above, but with reference population in memory where catvar = "nation"
dstdize v1 v2 svar, by(catvar) base("nation")

## Indirect standardization

Use population cases and size saved in cases and pop to standardize study cases v3 and stratum size v4 at each level of svar
istdize v3 v4 svar using mypop.dta, popvars(cases pop)
Same as above, but standardize subpopulations identified by levels of catvar
isdize v3 v4 svar using mypop.dta, popvars (cases pop) by (catvar)
Same as above, but standardize by population stratum-specific and crude rates saved in srate and crate and display summary of standard population
isdize v3 v4 svar using mypop.dta, rate(srate crate) by (catvar) print
Same as above, but indicate that the crude population rate is 0.01
isdize v3 v4 svar using mypop.dta, rate(srate .01) by (catvar) print

## Menu

dstdize
Statistics $>$ Epidemiology and related $>$ Other $>$ Direct standardization
istdize
Statistics $>$ Epidemiology and related $>$ Other $>$ Indirect standardization

## Syntax

Direct standardization dstdize charvar popvar stratavars [if] [in], by (groupvars) [dstdize_options]

Indirect standardization
istdize casevar popvar $_{s}$ stratavars [if] [in] using filename,
$\left\{\right.$ popvars $^{\left.\left(\text {casevar }_{p} \text { popvar }_{p}\right) \mid \operatorname{rate}\left(\text { ratevar }_{p}\left\{\# \mid \text { crudevar }_{p}\right\}\right)\right\}}$
[istdize_options]
charvar is the characteristic to be standardized across different subpopulations identified by groupvars. popvar defines the weights used in standardization.
stratavars defines the strata across which the weights are to be averaged in dstdize. For istdize, stratavars defines the strata for which casevar $_{s}$ is measured.
casevar $_{s}$ is the variable name for the study population's number of cases. If by (groupvars) is specified, casevar ${ }_{s}$ must be constant or missing within each group defined by combinations of groupvars.
popvar ${ }_{s}$ identifies the number of subjects in each strata in the study population.
filename must be a Stata dataset and contain popvar and stratavars.
dstdize_options

## Main

* by (groupvars)
using (filename)
base(\#| string)
level(\#)
Options
saving (filename)
format ( $\%$ fmt)
print
nores

Description
study populations
use standard population from Stata dataset use standard population from a value of grouping variable set confidence level; default is level(95)
save computed standard population distribution as a Stata dataset final summary table display format; default is $\% 10.0 \mathrm{~g}$ include table summary of standard population in output suppress storing results in $r()$
*by (groupvars) is required.
istdize_options Description
Main

* popvars (casevar popvar $_{p}$ )
for standard population, casevar $_{p}$ is number of cases and popvar ${ }_{p}$ is number of individuals
${ }^{*}$ rate ( ratevar $_{p}\left\{\# \mid\right.$ crudevar $\left._{p}\right\}$ ) ratevar $_{p}$ is stratum-specific rates and \# or crudevar ${ }_{p}$ is the crude case rate value or variable
level(\#)
set confidence level; default is level (95)
Options
by (groupvars)
variables identifying study populations
format ( $\%$ fmt)
final summary table display format; default is $\% 10.0 \mathrm{~g}$
print include table summary of standard population in output
*Either popvars $\left(\right.$ casevar $_{p}$ popvar $\left._{p}\right)$ or rate $\left(\operatorname{ratevar}_{p}\left\{\# \mid\right.\right.$ crudevar $\left.\left._{p}\right\}\right)$ must be specified.
collect is allowed with dstdize and istdize; see [U] 11.1.10 Prefix commands.

## Options for dstdize

$\qquad$ Main
by (groupvars) is required for the dstdize command; it specifies the variables identifying the study populations. If base () is also specified, there must be only one variable in the by () group. If you do not have a variable for this option, you can generate one by using something like generate newvar=1 and then use newvar as the argument to this option.
using(filename) or base (\#|string) may be used to specify the standard population. You may not specify both options. using (filename) supplies the name of a .dta file containing the standard population. The standard population must contain the popvar and the stratavars. If using() is not specified, the standard population distribution will be obtained from the data. base (\#|string) lets you specify one of the values of groupvar-either a numeric value or a string-to be used as the standard population. If neither base() nor using() is specified, the entire dataset is used to determine an estimate of the standard population.
level(\#) specifies the confidence level, as a percentage, for a confidence interval of the adjusted rate. The default is level (95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

Options
saving (filename) saves the computed standard population distribution as a Stata dataset that can be used in further analyses.
format (\% fmt) specifies the format in which to display the final summary table. The default is $\% 10.0 \mathrm{~g}$.
print includes a table summary of the standard population before displaying the study population results.
nores suppresses storing results in $r()$. This option is seldom specified. Some results are stored in matrices. If there are more groups than can fit in a matrix, dstdize will report the "unable to allocate matrix" error message. In this case, you must specify nores. The nores option does not change how results are calculated but specifies that results need not be left behind for use by other programs.

## Options for istdize

$\qquad$ Main
popvars (casevar popvar $_{p}$ ) or rate (ratevar $\left\{\# \mid\right.$ crudevar $\left._{p}\right\}$ ) must be specified with istdize. Only one of these two options is allowed. These options are used to describe the standard population's data.
With popvars (casevar popvar $_{p}$ ), casevar $_{p}$ records the number of cases (deaths) for each stratum in the standard population, and popvar ${ }_{p}$ records the total number of individuals in each stratum (individuals at risk).
With rate (ratevar ${ }_{p}\left\{\# \mid\right.$ crudevar $\left._{p}\right\}$ ), ratevar $_{p}$ contains the stratum-specific rates. \#|crudevar ${ }_{p}$ specifies the crude case rate either by a variable name or by the crude case rate value. If a crude rate variable is used, it must be the same for all observations, although it could be missing for some.
level(\#) specifies the confidence level, as a percentage, for a confidence interval of the adjusted rate. The default is level (95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.
by (groupvars) specifies variables identifying study populations when more than one exists in the data. If this option is not specified, the entire study population is treated as one group.
format (\%fmt) specifies the format in which to display the final summary table. The default is $\% 10.0 \mathrm{~g}$.
print outputs a table summary of the standard population before displaying the study population results.

## Remarks and examples

Remarks are presented under the following headings:

## Direct standardization

Indirect standardization
In epidemiology and other fields, you will often need to compare rates for some characteristic across different populations. These populations often differ on factors associated with the characteristic under study; thus, directly comparing overall rates may be misleading.

See van Belle et al. (2004, 642-684), Fleiss, Levin, and Paik (2003, chap. 19), or Kirkwood and Sterne (2003, chap. 25) for a discussion of direct and indirect standardization.

## Direct standardization

The direct method of adjusting for differences among populations involves computing the overall rates that would result if, instead of having different distributions, all populations had the same standard distribution. The standardized rate is defined as a weighted average of the stratum-specific rates, with the weights taken from the standard distribution. Direct standardization may be applied only when the specific rates for a given population are available.
dstdize generates adjusted summary measures of occurrence, which can be used to compare prevalence, incidence, or mortality rates between populations that may differ on certain characteristics (for example, age, gender, race). These underlying differences may affect the crude prevalence, mortality, or incidence rates.
> Example 1
We have data (Rothman 1986, 42) on mortality rates for Sweden and Panama for 1962, and we wish to compare mortality in these two countries:

| . use https://www.stata-press.com/data/r18/mortality (1962 Mortality, Sweden \& Panama) <br> . describe |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Contains data from https://www.stata-press.com/data/r18/mortality.dta |  |  |  |  |
| Observations: |  | 6 |  | 1962 Mortality, Sweden \& Panama |
| Variables: |  | 4 |  | 14 Apr 2022 16:18 |
| Variable name | Storage type | Display format | Value label | Variable label |
| nation | str6 | \%9s |  | Nation |
| age_category | byte | \%9.0g | age_lbl | Age category |
| population | float | \%10.0gc |  | Population in age category |
| deaths | float | \%9.0gc |  | Deaths in age category |

. list, sepby(nation) abbrev(12) divider

| nation | age_category | population | deaths |
| :--- | ---: | ---: | ---: |
| Sweden | $0-29$ | 3145000 | 3,523 |
| Sweden | $30-59$ | 3057000 | 10,928 |
| Sweden | $60+$ | 1294000 | 59,104 |
| Panama | $0-29$ | 741,000 | 3,904 |
| Panama | $30-59$ | 275,000 | 1,421 |
| Panama | $60+$ | 59,000 | 2,456 |

We divide the total number of cases in the population by the population to obtain the crude rate:
. collapse (sum) pop deaths, by (nation)
. list, abbrev(10) divider

|  | nation | population | deaths |
| :--- | :--- | ---: | ---: |
| 1. | Panama | 1075000 | 7,781 |
| 2. | Sweden | 7496000 | 73,555 |

. generate crude = deaths/pop
. list, abbrev(10) divider

| nation | population | deaths | crude |
| :---: | ---: | ---: | ---: |
| Panama | 1075000 | 7,781 | .0072381 |
| Sweden | 7496000 | 73,555 | .0098126 |

If we examine the total number of deaths in the two nations, the total crude mortality rate in Sweden is higher than that in Panama. From the original data, we see one possible explanation: Swedes are older than Panamanians, making direct comparison of the mortality rates difficult.

Direct standardization lets us remove the distortion caused by the different age distributions. The adjusted rate is defined as the weighted sum of the crude rates, where the weights are given by the standard distribution. Suppose that we wish to standardize these mortality rates to the following age distribution:

```
. use https://www.stata-press.com/data/r18/1962, clear
(Standard population distribution)
. list, abbrev(12) divider
```

|  | age_category | population |
| ---: | ---: | ---: |
| 1. | $0-29$ | .35 |
| 2. | $30-59$ | .35 |
| 3. | $60+$ | .3 |

. save 1962
file 1962.dta saved

If we multiply the above weights for the age strata by the crude rate for the corresponding age category, the sum gives us the standardized rate.

```
. use https://www.stata-press.com/data/r18/mortality
(1962 Mortality, Sweden & Panama)
```

```
. generate crude=deaths/pop
. drop pop
. merge m:1 age_cat using 1962
\begin{tabular}{lrl} 
Result & Number of obs & \\
\hline Not matched & 0 & \\
Matched & 6 & (_merge==3)
\end{tabular}
. list, sepby(age_category) abbrev(12)
```

|  | nation | age_category | deaths | crude | population | _merge |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: |
| 1. | Sweden | $0-29$ | 3,523 | .0011202 | .35 | Matched (3) |
| 2. | Panama | $0-29$ | 3,904 | .0052686 | .35 | Matched (3) |
|  | 3. | Panama | $30-59$ | 1,421 | .0051673 | .35 |
| 4. Matched (3) |  |  |  |  |  |  |
| 4. | Sweden | $30-59$ | 10,928 | .0035747 | .35 | Matched (3) |
|  | Panama | $60+$ | 2,456 | .0416271 | .3 | Matched (3) |
| 6. | Sweden | $60+$ | 59,104 | .0456754 | .3 | Matched (3) |

. generate product = crude*pop
. by nation, sort: egen adj_rate = sum(product)
. drop _merge
. list, sepby(nation)

|  | nation | age_ca~y | deaths | crude | popula~n | product | adj_rate |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: |
|  | 1. | Panama | $60+$ | 2,456 | .0416271 | .3 | .0124881 |
| 2. | Panama | $30-59$ | 1,421 | .0051673 | .0161407 |  |  |
| 3. | Panama | $0-29$ | 3,904 | .0052686 | .35 | .0018085 | .0161407 |
|  |  |  |  |  | .001844 | .0161407 |  |
|  | Sweden | $60+$ | 59,104 | .0456754 | .3 | .0137026 | .0153459 |
| 5. | Sweden | $30-59$ | 10,928 | .0035747 | .35 | .0012512 | .0153459 |
| 6. | Sweden | $0-29$ | 3,523 | .0011202 | .35 | .0003921 | .0153459 |

Comparing the standardized rates indicates that the Swedes have a slightly lower mortality rate.

To perform the above analysis with dstdize, type

```
. use https://www.stata-press.com/data/r18/mortality, clear
(1962 Mortality, Sweden & Panama)
. dstdize deaths pop age_cat, by(nation) using(1962)
Direct standardization
```

Summary of study populations

| nation | N | Crude rate | Adjusted rate | $[95 \%$ conf . interval] |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Panama | $1,075,000$ | 0.007238 | 0.016141 | 0.015645 | 0.016637 |
| Sweden | $7,496,000$ | 0.009813 | 0.015346 | 0.015235 | 0.015457 |

The summary table above lets us make a quick inspection of the results within the study populations, and the detail tables give the behavior among the strata within the study populations.

## Example 2

We have individual-level data on persons in four cities over several years. Included in the data is a variable indicating whether the person has high blood pressure, together with information on the person's age, sex, and race. We wish to obtain standardized high blood pressure rates for each city for 1990 and 1992, using, as the standard, the age, sex, and race distribution of the four cities and two years combined.

Our dataset contains

| Contains data from https://www.stata-press.com/data/r18/hbp.dta Observations:$1,130$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Variable name | Storage type | Display format | Value label | Variable label |
| id | str10 | \%10s |  | Record identification number |
| city | byte | \%8.0g |  | City |
| year | int | \%8.0g |  | Year |
| sex | byte | \%8.0g | sexfmt | Sex |
| age_group | byte | \%8.0g | agefmt | Age group |
| race | byte | \%8.0g | racefmt | Race |
| hbp | byte | \%8.0g | yn | High blood pressure |

Sorted by:
The dstdize command is designed to work with aggregate data but will work with individuallevel data only if we create a variable recording the population represented by each observation. For individual-level data, this is one:

```
. generate pop = 1
```

On the next page, we specify print to obtain a listing of the standard population and level (90) to request $90 \%$ rather than $95 \%$ confidence intervals. Typing if year==1990| year==1992 restricts the data to the two years for both summary tables and the standard population.
. dstdize hbp pop age race sex if year==1990 | year==1992, by(city year) print > level (90)

## Indirect standardization

Standardization of rates can be performed via the indirect method whenever the stratum-specific rates are either unknown or unreliable. If the stratum-specific rates are known, the direct standardization method is preferred.

To apply the indirect method, you must have the following information:

- The observed number of cases in each population to be standardized, $O$. For example, if deathrates in two states are being standardized using the US deathrate for the same period, you must know the total number of deaths in each state.
- The distribution across the various strata for the population being studied, $n_{1}, \ldots, n_{k}$. If you are standardizing the deathrate in the two states, adjusting for age, you must know the number of individuals in each of the $k$ age groups.
- The stratum-specific rates for the standard population, $p_{1}, \ldots, p_{k}$. For example, you must have the US deathrate for each stratum (age group).
- The crude rate of the standard population, $C$. For example, you must have the uS mortality rate for the year.

The indirect adjusted rate is then

$$
R_{\text {indirect }}=C \frac{O}{E}
$$

where $E$ is the expected number of cases (deaths) in each population. See Methods and formulas for a more detailed description of calculations.

## > Example 3

This example is borrowed from Kahn and Sempos (1989, 95-105). We want to compare 1970 mortality rates in California and Maine, adjusting for age. Although we have age-specific population counts for the two states, we lack age-specific deathrates. Direct standardization is not feasible here. We can use the US population census data for the same year to produce indirectly standardized rates for these two states.

From the US census, the standard population for this example was entered into Stata and saved in popkahn.dta.

```
. use https://www.stata-press.com/data/r18/popkahn, clear
. list age pop deaths rate, sep(4)
```

| age | population | deaths | rate |
| ---: | ---: | ---: | ---: |
| $<15$ | $57,900,000$ | 103,062 | .00178 |
| $15-24$ | $35,441,000$ | 45,261 | .00128 |
| $25-34$ | $24,907,000$ | 39,193 | .00157 |
| $35-44$ | $23,088,000$ | 72,617 | .00315 |
| $45-54$ | $23,220,000$ | 169,517 | .0073 |
| $55-64$ | $18,590,000$ | 308,373 | .01659 |
| $65-74$ | $12,436,000$ | 445,531 | .03583 |
| $75+$ | $7,630,000$ | 736,758 | .09656 |

The standard population contains for each age stratum the total number of individuals (pop) and both the age-specific mortality rate (rate) and the number of deaths. The standard population need not contain all three. If we have only the age-specific mortality rate, we can use the rate (ratevar ${ }_{p}$ crudevar $_{p}$ ) or rate (ratevar ${ }_{p} \#$ ) option, where crudevar $_{p}$ refers to the variable containing the total population's crude deathrate or \# is the total population's crude deathrate.

Now, let's look at the states' data (study population):

```
. use https://www.stata-press.com/data/r18/kahn
. list, sep(4)
```

| state | age | populat~n | death | st | death_~e |
| :--- | ---: | ---: | ---: | ---: | ---: |
| California | $<15$ | $5,524,000$ | 166,285 | 1 | .0016 |
| California | $15-24$ | $3,558,000$ | 166,285 | 1 | .0013 |
| California | $25-34$ | $2,677,000$ | 166,285 | 1 | .0015 |
| California | $35-44$ | $2,359,000$ | 166,285 | 1 | .0028 |
| California | $45-54$ | $2,330,000$ | 166,285 | 1 | .0067 |
| California | $55-64$ | $1,704,000$ | 166,285 | 1 | .0154 |
| California | $65-74$ | $1,105,000$ | 166,285 | 1 | .0328 |
| California | $75+$ | 696,000 | 166,285 | 1 | .0917 |
| Maine | $<15$ | 286,000 | 11,051 | 2 | .0019 |
| Maine | $15-24$ | 168,000 | . | 2 | .0011 |
| Maine | $25-34$ | 110,000 | . | 2 | .0014 |
| Maine | $35-44$ | 109,000 | . | 2 | .0029 |
| Maine | $45-54$ | 110,000 | . | 2 | .0069 |
| Maine | $55-64$ | 94,000 | . | 2 | .0173 |
| Maine | $65-74$ | 69,000 | . | 2 | .039 |
| Maine | $75+$ | 46,000 | . | 2 | .1041 |

For each state, the number of individuals in each stratum (age group) is contained in the pop variable. The death variable is the total number of deaths observed in the state during the year. It must have the same value for all observations in the group, as for California, or it could be missing in all but one observation per group, as for Maine.

To match these two datasets, the strata variables must have the same name in both datasets and ideally the same levels. If a level is missing from either dataset, that level will not be included in the standardization.

With kahn.dta in memory, we now execute the command. We will use the print option to obtain the standard population's summary table, and because we have both the standard population's age-specific count and deaths, we will specify the popvars (casevar popvar $_{p}$ ) option. Or, we could specify the rate (rate 0.00945 ) option because we know that 0.00945 is the US crude deathrate for 1970.

$r$ (lb_smr) $\quad 1 \times k$ vector of lower bounds of confidence intervals for SMRs

## Methods and formulas

The directly standardized rate, $S_{\mathrm{R}}$, is defined by

$$
S_{\mathrm{R}}=\frac{\sum_{i=1}^{k} w_{i} R_{i}}{\sum_{i=1}^{k} w_{i}}
$$

(Rothman 1986, 44), where $R_{i}$ is the stratum-specific rate in stratum $i$ and $w_{i}$ is the weight for stratum $i$ derived from the standard population.

If $n_{i}$ is the population of stratum $i$, the standard error, $\operatorname{se}\left(S_{\mathrm{R}}\right)$, in stratified sampling for proportions (ignoring the finite population correction) is

$$
\operatorname{se}\left(S_{\mathrm{R}}\right)=\frac{1}{\sum w_{i}} \sqrt{\sum_{i=1}^{k} \frac{w_{i}^{2} R_{i}\left(1-R_{i}\right)}{n_{i}}}
$$

(Cochran 1977, 108), from which the confidence intervals are calculated.
For indirect standardization, define $O$ as the observed number of cases in each population to be standardized; $n_{1}, \ldots, n_{k}$ as the distribution across the various strata for the population being studied; $R_{1}, \ldots, R_{k}$ as the stratum-specific rates for the standard population; and $C$ as the crude rate of the standard population. The expected number of cases (deaths), $E$, in each population is obtained by applying the standard population stratum-specific rates, $R_{1}, \ldots, R_{k}$, to the study populations:

$$
E=\sum_{i=1}^{k} n_{i} R_{i}
$$

The indirectly adjusted rate is then

$$
R_{\text {indirect }}=C \frac{O}{E}
$$

and $O / E$ is the study population's SMR if death is the event of interest or the SIR for studies of disease (or other) incidence.

The exact confidence interval is calculated for each estimated SMR by assuming a Poisson process as described in Breslow and Day (1987, 69-71). These intervals are obtained by first calculating the upper and lower bounds for the confidence interval of the Poisson-distributed observed events, $O$-say, $L$ and $U$, respectively-and then computing $\operatorname{SMR}_{L}=L / E$ and $\operatorname{SMR}_{U}=U / E$.

## Title

dtable - Create a table of descriptive statistics

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Methods and formulas | Appendix |
| Acknowledgments | Reference | Also see |  |

## Description

The dtable command allows you to easily create a table of descriptive (summary) statistics, commonly known as "Table 1 ". Optionally, you can add $p$-values from test statistics comparing groups on summary statistics. You can also create a table complete with a title, notes, and more, and then export it to a variety of file types.

## Quick start

Create a table describing continuous variables $x 1$ and $x 2$ and factor variables $f 1$ and $f 2$ dtable x1 x2 i.f1 i.f2

Same as above, but report statistics for each level of variable group, with and without the total sample
dtable x1 x2 i.f1 i.f2, by (group)
dtable x1 x2 i.f1 i.f2, by(group, nototals)
Same as above, but test each variable for equality between groups using linear regressions for continuous variables and Pearson $\chi^{2}$ tests for factor variables
dtable x1 x2 i.f1 i.f2, by (group, tests)
Same as above, but rather than putting sample frequencies in the first row, put them in the column header under each group label

```
dtable x1 x2 i.f1 i.f2, by(group, tests) sample(, place(seplabels))
```

Create a table of the median and interquartile interval for variables $\mathrm{x} 1-\mathrm{x} 4$

```
dtable, continuous(x1-x4, statistics(q2 iqi)) ///
    define(iqi = q1 q3) sformat("[%s]" iqi)
```

Same as above, but add the Kruskal-Wallis test for equality between levels of variable group

```
dtable, continuous(x1-x4, statistics(q2 iqi) test(kwallis)) ///
    define(iqi = q1 q3) sformat("[%s]" iqi) by(group, tests)
```

Create a table to describe variables using survey weights
dtable x* i.f*, svy
Same as above, but restrict the sample to the subpopulation where group equals 4
dtable x* i.f*, svy subpop(if group==4)

## Menu

| append | append to an existing file |

varlist may contain i. notation, including level selection. Time-series operators and interactions are not allowed.
fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
results is a list of names taken from nstats, cstats, ctest, fstats, ftest, and composite results.
hvalue may be left, center, or right.
fontfamily specifies a valid font family.
unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.
variant may be allcaps, smallcaps, or normal.
variant (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, LATEX, and HTML files.
variant (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, ${ }^{\text {ETSX}}$, and HTML files.
variant (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, LATEX, and HTML files.
upattern may be any of the patterns listed in the Appendix. For example, underline (none) removes the underline from the text, and underline (single) underlines the text. All other upatterns are available only when publishing items from a collection to Microsoft Word.
smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.
latex specifies the name of a $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ macro to render text for $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ output. Example $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ macro names are textbf, textsf, textrm, and texttt. Custom LATEX macros are also allowed. If text is to be rendered in a cell, title, or note, then latex is translated to the following when you export to $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ :
$\backslash$ latex $\{$ text $\}$
sspec is
[background(bgcolor) foreground(fgcolor) pattern(fpattern)]
bgcolor specifies the background color.
fgcolor specifies the foreground color.
fpattern specifies the fill pattern. A complete list of fill patterns is shown in the Appendix.
bgcolor, fgcolor, and color may be one of the colors listed in the Appendix; a valid RGB value in the form \#\#\# \#\#\# \#\#\#, for example, 171248 103; or a valid RRGGBB hex value in the form \#\#\#\#\#\#, for example, ABF867.
sfint is the specification for a string format in option sformat () and may contain a mix of text and $\%$ s. Here $\%$ s refers to the statistic value that is formatted as specified using nformat (). The text will be placed around the statistic as it is placed around $\% s$ in this option. For instance, to place parentheses around the statistic, you can specify sformat (" (\%s)").
Two text characters must be specified using a special character sequence if you want them to be displayed in your collection. To include $\%$, type $\% \%$. To include $\backslash$, type $\backslash \backslash$. For instance, to place a percent sign after a statistic, you can specify sformat("\%s\%\%").

## Options

$\underset{\text { by (varname }[\text {, by_opts }] \text { ) specifies that the statistics be displayed separately for each unique value }}{\text { Main }}$ of varname; varname may be numeric or string.
by_opts are the following:
tests and notests specify whether to show the tests comparing groups. tests displays the tests comparing groups; notests suppresses them.
When tests is combined with the missing suboption, the test will be performed with the missing values composing an additional group. By default, missing values are excluded from tests.
testnotes and notestnotes specify whether to show a note detailing each test comparing groups. testnotes displays the notes; notestnotes suppresses them.
totals and nototals specify whether to show the statistics for the total sample. totals displays the statistics for the total sample; nototals suppresses them.
missing and nomissing specify whether to show numeric missing values in varname. missing displays the numeric missing values; nomissing suppresses them.
When missing is combined with the tests suboption, missing values will also be included in the test performed. By default, missing values are excluded from tests.
column (col_opts) specifies the column header styles and titles. col_opts are one or more of the following.
summary ([title][, [no]hide halign(hvalue) text_styles $]$ ) specifies the column header and styles when global option by () is not specified. The default title is Summary.
hide and nohide specify whether to show the title. hide suppresses the title; nohide displays the title.
halign(hvalue) specifies how the column header cell is horizontally aligned. hvalue may be left, center, or right.
text_styles affect the text styles for the column header.
by ([by_style][, [no]fvlabel halign(hvalue) text_styles]) specifies the by() variable's column header and styles.
by_style specifies the column header style for the by () variable. by_style may be label, name, or hide.
label specifies that the by () variable's label be used. If the by () variable does not have a label, then the name is used.
name specifies that the by () variable's name be used.
hide specifies that the by () variable not be shown in the column header.
fvlabel and nofvlabel specify whether value labels for the levels of the by () variable should be displayed. fvlabel displays the value labels; nofvlabel displays the values.
halign(hvalue) specifies how the column header cells are horizontally aligned. hvalue may be left, center, or right.
text_styles affect the text styles for the column header.
test ([title][, [no]hide halign(hvalue) text_styles $]$ ) specifies the column header and text styles for the test column. The default title is Test.
hide and nohide specify whether to show the title for the test column. hide suppresses the title; nohide displays the title.
halign(hvalue) specifies how the test column header cell is horizontally aligned. hvalue may be left, center, or right.
text_styles affect the text styles for the test column header.
total ([title $][,[$ no $]$ hide halign(hvalue) text_styles $]$ ) specifies the column header and text styles for the total sample. The default title is Total.
hide and nohide specify whether to show the title for the total sample. hide suppresses the title; nohide displays the title.
halign(hvalue) specifies how the total sample column header cell is horizontally aligned. hvalue may be left, center, or right.
text_styles affect the text styles for the total sample column header.
text_styles are font ([fontfamily] [, font_opts]), smcl(smcl), latex (latex), and shading(sspec).
font ([fontfamily] [, size(\# [unit]) color(color) variant (variant) [no]bold
[no]italic [no]strikeout [no]underline underline(upattern)]) specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and LATEX files, unless otherwise specified.
fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
$\operatorname{size}(\#[$ unit $]$ ) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
color (color) specifies the text color.
variant (variant) specifies the font variant and capitalization.
bold and nobold specify the font weight. bold changes the font weight to bold; nobold changes the font weight back to normal.
italic and noitalic specify the font style. italic changes the font style to italic; noitalic changes the font style back to normal.
strikeout and nostrikeout specify whether to add a strikeout mark to the text. strikeout adds a strikeout mark to the text; nostrikeout changes the text back to normal.
underline (upattern), underline, and nounderline specify how to underline the text.
Only one of strikeout or underline is allowed when publishing to HTML files.
$\operatorname{smcl}(s m c l)$ specifies how to render the text for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.
latex (latex) specifies how to render the text for $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ output. This style property is applicable only when publishing items from a collection to a $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ file.
shading (sspec) sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and ${ }^{L A T} T_{E} \mathrm{X}$ files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Survey
svy specifies that dtable use the survey design information from svyset. This means all statistics will be computed using the specified survey weights, where applicable. This option changes the list of supported tests in continuous() and factor().
$\operatorname{subpop}([$ varname $][$ if $]$ ) specifies that estimates be computed for the single subpopulation identified by the observations for which varname $\neq 0$ and that also meet the if conditions. Typically, varname $=1$ defines the subpopulation, and varname $=0$ indicates observations not belonging to the subpopulation. For observations whose subpopulation status is uncertain, varname should be set to a missing value; such observations are dropped from the estimation sample. This option implies the svy option.
See [SVY] Subpopulation estimation for more information.
nosample and sample() control the display of sample frequency statistics. nosample prevents reporting any sample frequency statistic.
sample([title] [, statistics(nstats) place(place) text_styles]) specifies sample frequency statistics, their row header title, and how they are composed in the table.
title specifies the row header for the sample frequency statistics. The default title is N . statistics (nstats) specifies the sample frequency statistics to report.
nstats may include the following sample frequency statistics and any composite result defined from them.

| nstats | Definition |
| :--- | :--- |
| $\frac{\text { frequency }}{\text { sumw }}$ | frequency <br> sum of weights |
| percent | percentage |
| proportion | proportion |
| rawpercent | unweighted percentage <br> unweighted proportion |

Without weights, the default sample frequency statistic is frequency.
With weights, the default sample frequency statistic is sumw.
With option by (), percent is added to the default sample frequency statistic. place (place) controls where the sample frequency statistics are reported in the table.
place(items), the default, specifies that the sample frequency statistics be reported in the first row of items in the table.
place (inlabels) specifies that the sample frequency statistics be added to the column header labels.
place (seplabels) specifies that the sample frequency statistics be stacked in the column header as separate labels.
text_styles specifies the text styles for title.

Continuous
continuous ( $\left[\right.$ varlist $\left._{c}\right][$, statistics (cstats) test (ctest) text_styles $]$ ) specifies continuous variables, their row header text styles, their statistics, and their test. If $\mathrm{varlist}_{c}$ is not specified, then the specified text styles, statistics, and test become the default for all continuous variables in varlist. This option is repeatable, and when multiple text styles, statistics, or tests apply to a variable, the rightmost specification is applied.
statistics(cstats) specifies the statistics to report for varlist $c_{c}$.
cstats may contain the following continuous variable statistics and any composite result defined from them.

| cstats | Description |
| :--- | :--- |
| mean | mean |
| semean | standard error of the mean |
| sebinomial | standard error of the mean, binomial <br> sepoisson |
| standard error of the mean, Poisson |  |
| variance | variance |
| sd | standard deviation |
| $\underline{\text { skewness }}$ | skewness |
| $\underline{\text { kurtosis }}$ | kurtosis |
| cv | coefficient of variation |
| svycv | coefficient of variation (svy) |
| geomean | geometric mean |
| geosd | geometric standard deviation |
| count | number of nonmissing values |
| median | median |
| p\# | \#th percentile |
| q1 | first quartile |
| q2 | second quartile |
| q3 | third quartile |
| iqr | interquartile range |
| min | minimum value |
| max | maximum value |
| range | range |
| first | first value |
| last | last value |
| firstnm | first nonmissing value |
| lastnm | last nonmissing value |
| total | total |
| $\underline{\text { rawtotal }}$ | unweighted total |

The default continuous variable statistics are mean and sd.
test (ctest) specifies that ctest be computed for the continuous variables in varlist. This option has no effect if the by () option is not specified.
ctest is one of the following:

| ctest | Description |
| :--- | :--- |
| regress | main effects test from a linear regression |
| poisson | main effects test from a Poisson regression |
| lnormal | main effects test from a log-normal regression |
| kwallis | Kruskal-Wallis rank test |
| kwallis_ties | Kruskal-Wallis rank test, adjusted for ties |
| none | suppress the test |

kwallis and kwallis_ties are not allowed with weights or the svy option.
The default test for continuous variables is regress.
For nonsurvey data, regress is equivalent to a one-way ANOVA, and when the by () variable has two levels, regress is equivalent to a pooled $t$ test.
text_styles specifies the row header text styles for varlist ${ }_{c}$.
$\qquad$ Factors
factor ([ varlist $\left.f_{f}\right][$, statistics (fstats) test (ftest) text_styles $]$ ) specifies factor variables, their row header text styles, their statistics, and their test. If varlist ${ }_{f}$ is not specified, then the specified text styles, statistics, and test become the default for all factor variables in varlist.

This option is repeatable, and when multiple text styles, statistics, or tests apply to a variable, the rightmost specification is applied.
statistics ( $f$ stats) specifies the statistics to report for varlist $_{f}$.
$f$ stats may contain the following factor-variable statistics and any composite result defined from them.

| fstats | Definition |
| :--- | :--- |
| fvfrequency frequency of each factor-variable level <br> fvpercent percentage within each factor-variable level <br> fvproportion proportion within each factor-variable level <br> fvrawfrequency unweighted frequency of each factor-variable level <br> fvrawpercent unweighted percentage within each factor-variable level <br> fvrawproportion unweighted proportion within each factor-variable level  |  |

The default factor-variable statistics are fvfrequency and fvpercent.
test (ftest) specifies that ftest be computed for the factor variables in varlist $f_{f}$. This option has no effect if the by () option is not specified.
ftest is one of the following:

| ftest | Description |
| :--- | :--- |
| pearson | Pearson's $\chi^{2}$ test |
| fisher | Fisher's exact test |
| lrchi2 | likelihood-ratio $\chi^{2}$ test |
| gamma | Goodman and Kruskal's gamma |
| kendall | Kendall's $\tau_{b}$ |
| cramer | Cramér's $V$ |
| svylr | survey-adjusted likelihood-ratio test <br> svywald <br> svyllwald |
| survey-adjusted Wald test |  |
| none | suppress the test |

fisher, lrchi2, gamma, kendall, and cramer are not allowed with aweights, iweights, pweights, or the svy option.
svylr, svywald, and svyllwald are allowed only with the svy option.
The default test for factor variables is pearson.
text_styles specifies the row header text styles for varlist $_{f}$.

Composite
define (name=elements [, def_opts]) defines a composite result. Composite results give more control over how statistics are composed and formatted in a table cell.
name is the name you choose for the new composite result.
elements is a list of statistics and other composite results.
def_opts are delimiter (char), [no]trim, [no]override, and replace.
delimiter (char) changes the delimiter between elements. The default is delimiter(" ").
notrim and trim control the handling of extra spaces caused by numeric formats applied to the elements. notrim preserves the extra spaces; trim, the default, removes the extra spaces.
nooverride and override control handling of the trim property when an element is a composite result. nooverride, the default, does not change the trim property of elements; override applies the specified trim property to all elements.
replace permits you to redefine name if it already exists.

Formats
nformat ( $\%$ fint [results][, basestyle]) changes the numeric format, such as the number of decimal places, for specified results. If results are not specified, the numeric format is changed for all results.
results is a list of names taken from nstats, cstats, ctest, fstats, ftest, and composite results.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.
This option does not affect the format of factor variables specified in varlist or the factor () option. The default format of these variables is taken from the dataset.
basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.
sformat (sfint [results]) changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.
sfmt may contain a mix of text and $\%$ s. Here $\%$ s refers to the numeric value that is formatted as specified using nformat (). The text will be placed around the numeric values in your table as it is placed around \%s in this option. For instance, to place parentheses around the percent statistics, you can specify sformat(" (\%s)" fvpercent percent).
results is a list of names taken from nstats, cstats, ctest, fstats, ftest, and composite results.
Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include $\%$, type $\% \%$. To include $\backslash$, type $\backslash \backslash$. For instance, to place a percent sign following percent statistics, you can specify sformat ( $\% \%$ s\% \% " fvpercent percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

## Title

title (string) adds the text string as a title to the table.
titlestyles (text_styles) changes the style for the table title. text_styles are the following:
font ([fontfamily] [, size(\# [unit]) color (color) variant (variant) [no]bold
[no]italic [no]strikeout [no]underline]) specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and LATEX files, unless otherwise specified.
fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
size (\# [unit]) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
color (color) specifies the text color.
variant (variant) specifies the font variant and capitalization.
bold and nobold specify the font weight. bold changes the font weight to bold; nobold changes the font weight back to normal.
italic and noitalic specify the font style. italic changes the font style to italic; noitalic changes the font style back to normal.
strikeout and nostrikeout specify whether to add a strikeout mark to the title. strikeout adds a strikeout mark to the title; nostrikeout changes the title back to normal.
underline and nounderline specify whether to underline the table title. underline adds a single line under the title; nounderline removes the underline.

Only one of strikeout or underline is allowed when publishing to HTML files.
$\mathrm{smcl}(\mathrm{smcl})$ specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.
latex (latex) specifies how to render the table title for $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ output. This style property is applicable only when publishing items from a collection to a ${ }^{\mathrm{AT}} \mathrm{E}_{\mathrm{E}} \mathrm{X}$ file.
shading (sspec) sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Notes
note (string) adds the text string as a note to the table. note() may be specified multiple times to add multiple notes. Each note is placed on a new line.
notestyles (text_styles) changes the style for the table notes. text_styles are the following:
font ([fontfamily] [, size(\# [unit]) color (color) variant (variant) [no]bold
[no]italic [no]strikeout [no]underline]) specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and LATEX files, unless otherwise specified.
fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
size (\# [unit]) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
color (color) specifies the text color.
variant (variant) specifies the font variant and capitalization.
bold and nobold specify the font weight. bold changes the font weight to bold; nobold changes the font weight back to normal.
italic and noitalic specify the font style. italic changes the font style to italic; noitalic changes the font style back to normal.
strikeout and nostrikeout specify whether to add a strikeout mark to the notes. strikeout adds a strikeout mark to the note; nostrikeout changes the note back to normal.
underline and nounderline specify whether to underline the table notes. underline adds a single line under the notes; nounderline removes the underline.

Only one of strikeout or underline is allowed when publishing to HTML files.
smcl ( smcl ) specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.
latex (latex) specifies how to render the table notes for $\mathrm{LAT}_{\mathrm{E} X}$ output. This style property is applicable only when publishing items from a collection to a $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ file.
shading (sspec) sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.
export (filename.suffix [, export_opts]) exports the table to the specified file. export_opts are the following:
as (fileformat) specifies the file format to which the table is to be exported. This option is rarely specified because, by default, dtable determines the format from the suffix of the file being created.
replace permits dtable to overwrite an existing file.
noisily specifies that dtable show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The putdocx, putexcel, or putpdf command used to export the table will be displayed.
dofile(filename [, replace]) specifies that dtable save to filename the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If filename already exists, it can be overwritten by specifying replace. If filename is specified without an extension, .do is assumed.
append specifies that dtable append the table to an existing file.
This option is applicable when you export the table to an HTML, a LATEX, a SMCL, a txt, or a Markdown file. When you export to HTML and $\mathrm{LA}_{\mathrm{E}} \mathrm{X}$ files, the append option implies the tableonly option. Furthermore, when you export to HTML files, if the target CSS file already exists, dtable will also append to it.
tableonly specifies that only the table be exported to the specified HTML or $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ document. By default, dtable produces complete HTML and $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ documents.

When you export to an HTML file, if the cssfile() option is not specified, a CSS filename is constructed from filename, with the extension replaced with .css.
cssfile(cssfile) specifies that dtable define the styles in cssfile instead of filename when you export to HTML.
prefix (prefix) specifies that dtable use prefix to identify style classes when you export to HTML.
sheet (sheetname [, replace]) saves to the worksheet named sheetname. For more information about this option, see [RPT] putexcel.
cell (cell) specifies an Excel upper-left cell as the starting position to publish the table. The default is cell(A1).
modify permits putexcel set to modify an Excel file. For more information about this option, see [RPT] putexcel.
noopen prevents putexcel from opening the Excel file in memory for modification. It does not appear on the dialog box. For more information about this option, see [RPT] putexcel.
varlabel and novarlabel specify whether variable labels for the continuous and factor variables should be displayed. varlabel displays the variable label; novarlabel displays variable names.
fvlabel and nofvlabel specify whether value labels for the factor variables should be displayed. fvlabel displays value labels; nofvlabel displays the values.
listwise and nolistwise specify how to handle missing values across the continuous and factor variables. listwise handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any continuous or factor variable is missing for that
observation; nolistwise specifies that dtable omit an observation only if all the continuous and factor variables are missing for that observation.
halign(hvalue) specifies how the item cells are horizontally aligned. hvalue may be left, center, or right.
name (cname) specifies the collection for dtable to work with. The default is name(DTable).
replace permits dtable to overwrite the existing collection. This option is implied for name (DTable).
label (filename) specifies the filename containing the collection labels to use for your table. Labels in filename will be loaded for the table, and default labels will be used for any labels not specified in filename.
style(filename[, override]) specifies the filename containing the collection styles to use for your table. This might be a style you saved with collect style save or a predefined style shipped with Stata. The dtable collection styles will be discarded, and only the collection styles in filename will be applied. Note that the layout specification saved in filename will not be applied; dtable will always use its predefined layout.
If you prefer the dtable collection styles but also want to apply any styles in filename, specify override. If there are conflicts between the default collection styles and those in filename, the ones in filename will take precedence.
The default is to use only the collection styles set in c(dtable_style); see [TABLES] set dtable_style.

The following option is available with dtable but is not shown in the dialog box:
warn specifies that dtable display warnings from collect. By default, these warnings are suppressed.

## Remarks and examples

Remarks are presented under the following headings:

Introduction<br>A first example<br>Describe variables across groups<br>Survey data<br>Save your style choices for next time<br>Composite results<br>The default style

## Introduction

dtable allows you to easily create a table of summary statistics and export it to a variety of file types, without any knowledge of the collection system. You can specify the continuous and factor variables that you want described in your table. You can also customize the table by formatting the results, changing the variable-specific statistics, adding a variable to identify sample groups, testing each variable for equality between groups, adding a title and notes, and more.

In most cases, you will use dtable to easily create a table and export it to another format. However, you can customize the table beyond the options that are available with dtable. When you issue a dtable command, the results are stored in a collection called DTable. This collection is replaced with each new dtable command, unless you specify a different name for the collection in the name () option. You can make additional changes to the collection with the collect suite of commands. To learn more about the collect commands, see [TABLES] Intro and the entries discussed therein.

## A first example

In its simplest specification, you type dtable and a list of variables you want described in your table. For our first example, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). Our table describes continuous variables for systolic blood pressure, age, weight, and factor variables for race and health status.

```
. use https://www.stata-press.com/data/r18/nhanes2l
(Second National Health and Nutrition Examination Survey)
. dtable bpsystol age weight i.race i.hlthstat
```

|  | Summary |  |
| :--- | ---: | ---: |
| N | 10,351 |  |
| Systolic blood pressure | $130.882(23.333)$ |  |
| Age (years) | $47.580(17.215)$ |  |
| Weight (kg) | 71.898 | $(15.356)$ |
| Race |  |  |
| White | $9,065(87.6 \%)$ |  |
| Black | $1,086(10.5 \%)$ |  |
| Other | $200(1.9 \%)$ |  |
| Health status |  |  |
| Excellent | $2,407(23.3 \%)$ |  |
| Very good | $2,591(25.1 \%)$ |  |
| Good | $2,938(28.4 \%)$ |  |
| Fair | $1,670(16.2 \%)$ |  |
| Poor | $729(7.1 \%)$ |  |

The default continuous variable statistics are the mean and standard deviation. The default factorvariable statistics are the factor-level frequencies and percentages. You can change the statistics reported for each continuous and factor variable; see the continuous() and factor() options for the list of supported statistics.

Many options are also available to change the formatting and style of your table. Here we set the format of means and standard deviations to show two decimal places, remove the first row of the table with the overall sample size, and change the column header to be more descriptive of the table results.

Additionally, you can complete your table with a title and notes and even export it to another format. We now add a title and export our table to the file mydtable.html.

```
. dtable bpsystol age weight i.race i.hlthstat,
> nformat(%16.2fc mean sd)
> nosample
> column(summary(M(SD) / n(%)))
> title(Table 1)
> export(mydtable.html)
Table 1
```

|  | M(SD) / n(\%) |
| :--- | ---: |
| Systolic blood pressure | $130.88(23.33)$ |
| Age (years) | $47.58(17.21)$ |
| Weight (kg) | $71.90(15.36)$ |
| Race |  |
| White | $9,065(87.6 \%)$ |
| Black | $1,086(10.5 \%)$ |
| Other | $200(1.9 \%)$ |
| Health status | $2,407(23.3 \%)$ |
| Excellent | $2,591(25.1 \%)$ |
| Very good | $2,938(28.4 \%)$ |
| Good | $1,670(16.2 \%)$ |
| Fair | $729(7.1 \%)$ |
| Poor |  |

We could also export this table to a Microsoft Word, Microsoft Excel, LATEX, Markdown, SMCL, PDF, or plain-text file by specifying the appropriate file extension.

## Describe variables across groups

Describing variables across samples in your dataset is easy with the by () option. In the following, we revisit our original table, but we add the by () option to get summary statistics from the urban, rural, and total samples.
. dtable bpsystol age weight i.race i.hlthstat, by(rural) sample(N (\%))

|  | Urban |  | Rural <br> Rural | Total |
| :--- | ---: | ---: | ---: | ---: |
| N (\%) | $6,548(63.3 \%)$ | $3,803(36.7 \%)$ | $10,351(100.0 \%)$ |  |
| Systolic blood pressure | $130.460(23.526)$ | $131.607(22.980)$ | $130.882(23.333)$ |  |
| Age (years) | $46.835(17.484)$ | $48.862(16.666)$ | $47.580(17.215)$ |  |
| Weight (kg) | $71.427(15.363)$ | $72.708(15.314)$ | $71.898(15.356)$ |  |
| Race |  |  |  |  |
| White | $5,419(82.8 \%)$ | $3,646(95.9 \%)$ | $9,065(87.6 \%)$ |  |
| Black | $968(14.8 \%)$ | $118(3.1 \%)$ | $1,086(10.5 \%)$ |  |
| Other | $161(2.5 \%)$ | $39(1.0 \%)$ | $200(1.9 \%)$ |  |
| Health status |  |  |  |  |
| Excellent | $1,609(24.6 \%)$ | $798(21.0 \%)$ | $2,407(23.3 \%)$ |  |
| Very good | $1,713(26.2 \%)$ | $878(23.1 \%)$ | $2,591(25.1 \%)$ |  |
| Good | $1,878(28.7 \%)$ | $1,060(27.9 \%)$ | $2,938(28.4 \%)$ |  |
| Fair | $950(14.5 \%)$ | $720(19.0 \%)$ | $1,670(16.2 \%)$ |  |
| Poor | $389(5.9 \%)$ | $340(9.0 \%)$ | $729(7.1 \%)$ |  |

Next, we add the tests suboption in the by () option to report tests of equality between samples and the nototals option to suppress the column of statistics from the total sample. We also specify that we would like sample statistics to be in the column headers rather than the first row of the table using the sample() option. Here we also add the column(by (hide)) option to suppress the redundant label from variable rural and add notes that detail what is being reported.

```
. dtable bpsystol age weight i.race i.hlthstat,
> by(rural, nototals tests)
> column(by(hide))
> sample(, place(seplabels))
> note(Mean (Standard deviation): p-value from a pooled t-test.)
> note(Frequency (Percent%): p-value from Pearson test.)
note: using test regress across levels of rural for bpsystol, age, and
    weight.
note: using test pearson across levels of rural for race and hlthstat.
```

|  | Urban |  | Rural |
| :--- | ---: | ---: | ---: |
|  | $6,548(63.3 \%)$ | $3,803(36.7 \%)$ | Test |
| Systolic blood pressure | $130.460(23.526)$ | $131.607(22.980)$ | 0.016 |
| Age (years) | $46.835(17.484)$ | $48.862(16.666)$ | $<0.001$ |
| Weight (kg) | $71.427(15.363)$ | $72.708(15.314)$ | $<0.001$ |
| Race |  |  |  |
| White | $5,419(82.8 \%)$ | $3,646(95.9 \%)$ | $<0.001$ |
| Black | $968(14.8 \%)$ | $118(3.1 \%)$ |  |
| Other | $161(2.5 \%)$ | $39(1.0 \%)$ |  |
| Health status |  |  |  |
| Excellent | $1,609(24.6 \%)$ | $798(21.0 \%)$ | $<0.001$ |
| Very good | $1,713(26.2 \%)$ | $878(23.1 \%)$ |  |
| Good | $1,878(28.7 \%)$ | $1,060(27.9 \%)$ |  |
| Fair | $950(14.5 \%)$ | $720(19.0 \%)$ |  |
| Poor | $389(5.9 \%)$ | $340(9.0 \%)$ |  |

Mean (Standard deviation) : p-value from a pooled t-test.
Frequency (Percent\%) : p-value from Pearson test.
For continuous variables, the Test column reports the $p$-value from linear regressions, which are equivalent to pooled $t$ tests because rural has two categories. For factor variables, the Test column reports the $p$-values from Pearson $\chi^{2}$ tests.

## Survey data

dtable supports survey data by using the survey data characteristics in your dataset when you specify the svy option. Your data must be svyset prior to calling dtable with the svy option. Our data already have survey data characteristics.

```
. svyset
Sampling weights: finalwgt
            VCE: linearized
    Single unit: missing
    Strata 1: strata
Sampling unit 1: psu
                FPC 1: <zero>
```

The following table reports the survey weighted frequency, mean, standard deviation, factor-level frequency, and factor-level percent of the specified variables.

```
. dtable bpsystol age weight i.race i.hlthstat, svy
```

|  | Summary |
| :--- | ---: |
| N | $117,157,513$ |
| Systolic blood pressure | $126.946(21.401)$ |
| Age (years) | $42.253(15.502)$ |
| Weight (kg) | $71.901 \quad(15.433)$ |
| Race |  |
| $\quad$ White | $102,999,549(87.9 \%)$ |
| $\quad$ Black | $11,189,236(9.6 \%)$ |
| Other | $2,968,728(2.5 \%)$ |
| Health status |  |
| $\quad$ Excellent | $32,187,335(27.5 \%)$ |
| Very good | $32,176,310(27.5 \%)$ |
| Good | $32,715,395(28.0 \%)$ |
| Fair | $14,380,261(12.3 \%)$ |
| Poor | $5,537,956(4.7 \%)$ |

Option by () is allowed with svy. dtable also has options for tests of equality between groups that are allowed with svy. These tests account for the survey data characteristics in your data. In the following, we revisit the urban and rural summary table, but we add the svy option, a title, and some notes. We also add the column(by (hide)) option to suppress the redundant label from variable rural and add the test () suboption to rename the Test column.

```
. dtable bpsystol age weight i.race i.hlthstat, svy
> by(rural, nototals tests)
> column(by(hide) test(p-value))
> title(Survey data summary)
> note(Mean (Standard deviation): p-value from linear regression.)
> note(Frequency (Percent%): p-value from Pearson test.)
> note(Statistics computed using the survey weights.)
> note(Tests adjusted for the survey design.)
note: using test regress across levels of rural for bpsystol, age, and
    weight.
note: using test pearson across levels of rural for race and hlthstat.
Survey data summary
```

|  | Urban | Rural | p-value |
| :---: | :---: | :---: | :---: |
| N | 79,965,794 (68.3\%) | 37,191,719 (31.7\%) |  |
| Systolic blood pressure | 126.607 (21.438) | 127.675 (21.305) | 0.406 |
| Age (years) | 41.805 (15.662) | 43.215 (15.112) | 0.024 |
| Weight (kg) | 71.322 (15.371) | 73.144 (15.493) | <0.001 |
| Race |  |  |  |
| White | 67,579,394 (84.5\%) | 35,420,155 (95.2\%) | <0.001 |
| Black | 9,936,159 (12.4\%) | 1,253,077 (3.4\%) |  |
| Other | 2,450,241 (3.1\%) | 518,487 (1.4\%) |  |
| Health status |  |  |  |
| Excellent | 22,781,784 (28.5\%) | 9,405,551 ( $25.3 \%$ ) | <0.001 |
| Very good | 22,867,496 (28.6\%) | 9,308,814 (25.1\%) |  |
| Good | 22,089,942 (27.7\%) | 10,625,453 (28.6\%) |  |
| Fair | 8,892,926 (11.1\%) | 5,487,335 (14.8\%) |  |
| Poor | 3,229,798 (4.0\%) | 2,308,158 (6.2\%) |  |

Mean (Standard deviation): p-value from linear regression.
Frequency (Percent\%) : p-value from Pearson test.
Statistics computed using the survey weights.
Tests adjusted for the survey design.

## Save your style choices for next time

If you find yourself repeating certain options each time you use dtable, you can save most of those option choices for future tables. Use collect style save to store your dtable option choices to a collection style file and then specify this file in the style() option the next time you use dtable. If you store the collection style file in your PERSONAL folder, you can set that file as the default style for dtable.

In the following, we use dtable to create a table with some option choices, save our style to a file in the PERSONAL directory, and set that style file as the default for dtable.

```
. sysuse auto
(1978 automobile data)
. dtable mpg turn i.rep78,
> sample(Sample, statistic(frequency) place(seplabels))
> sformat("n=%s" frequency)
> by(foreign, tests nototals missing)
> continuous(, test(kwallis))
> factor(, test(pearson))
> title(Table 1. Summary by group with a test.)
> note(Kruskal-Wallis test for continuous variables.)
> note(Pearson's test for factor variables.)
note: using test kwallis across levels of foreign for mpg and turn.
note: using test pearson across levels of foreign for rep78.
Table 1. Summary by group with a test.
```

|  | Domestic <br> $\mathrm{n}=52$ |  | Car origin <br> Foreign <br> $\mathrm{n}=22$ | Test |
| :--- | ---: | ---: | ---: | ---: |
| Mileage (mpg) | $19.827(4.743)$ | $24.773(6.611)$ | 0.002 |  |
| Turn circle (ft.) | $41.442(3.968)$ | $35.409(1.501)$ | $<0.001$ |  |
| Repair record 1978 |  |  |  |  |
| 1 | $2(4.2 \%)$ | $0(0.0 \%)$ | $<0.001$ |  |
| 2 | $8(16.7 \%)$ | $0(0.0 \%)$ |  |  |
| 3 | $27(56.2 \%)$ | $3(14.3 \%)$ |  |  |
| 4 | $9(18.8 \%)$ | $9(42.9 \%)$ |  |  |
| 5 | $2(4.2 \%)$ | $9(42.9 \%)$ |  |  |

```
Kruskal-Wallis test for continuous variables.
Pearson's test for factor variables.
. personal dir
your personal ado-directory is C:\ado\personal\
    (output omitted)
. collect style save "C:\ado\personal\mydtable"
(style from DTable saved to file C:\ado\personal\mydtable.stjson)
. set dtable_style mydtable
. display c(dtable_style)
mydtable
```

Now these style choices are the defaults for tables created in the future. Here we create a similarly styled table but from different data.

```
. use https://www.stata-press.com/data/r18/lbw
(Hosmer & Lemeshow data)
. dtable age i.smoke i.ht, by(low)
note: using test kwallis across levels of low for age.
note: using test pearson across levels of low for smoke and ht.
Table 1. Summary by group with a test.
```

|  | Birthweight<2500g |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\begin{gathered} 0 \\ \mathrm{n}=130 \end{gathered}$ | $\begin{gathered} 1 \\ \mathrm{n}=59 \end{gathered}$ |  | Test |
|  |  |  |  |  |
| Age of mother | 23.662 (5.585) | 22.305 | (4.511) | 0.248 |
| Smoked during pregnancy |  |  |  |  |
| Nonsmoker | 86 (66.2\%) | 29 | (49.2\%) | 0.026 |
| Smoker | 44 (33.8\%) | 30 | (50.8\%) |  |
| Has history of hypertension |  |  |  |  |
| 0 | 125 (96.2\%) | 52 | (88.1\%) | 0.036 |
| 1 | 5 (3.8\%) | 7 | (11.9\%) |  |

Kruskal-Wallis test for continuous variables.
Pearson's test for factor variables.
To reset the dtable style back to its original default, type
. set dtable_style dtable
You can add the permanently option to set the default dtable style for future Stata sessions.

## Composite results

dtable's default style does not define any composite results, so you will need to define your own with the define() option. Stata has a collection style named dtable_composites that defines the following composite results for you.

| composite | elements | Description |
| :--- | :--- | :--- |
| idi | p10 p90 | Interdecile interval |
| iqi | q1 q3 | Interquartile interval |
| rangei | min max | Range interval |

All of these results are bound in square brackets without a delimiter between their elements. To get access to these composite results, use the style(dtable_composites, override) option. You can then specify idi, iqi, and rangei in the statistic() suboption of continuous(), just as you would any other statistic.

You may want different formatting for these composite results, or you may want to create composite results based on other statistics. The define() option allows you to customize your own composite results. In the following, we use dtable to create a table that defines our own interval results with some other option choices and then save the collection's style to a file.

```
. sysuse auto
(1978 automobile data)
. dtable, define(idi = p10 p90, delimiter("; "))
> define(iqi = q1 q3, delimiter("; "))
> define(rangei = min max, delimiter("; "))
> sample(Sample, statistic(frequency) place(seplabels))
> sformat("n=%s" frequency)
> sformat("{%s}" idi)
> sformat("[%s]" iqi)
> sformat("<%s>" rangei)
> continuous(mpg, statistic(p50 idi))
> continuous(turn, statistic(q2 iqi))
> continuous(trunk, statistic(mean rangei))
> title(Table 1. Location and interval.)
> note(Median {Interdecile interval})
> note(Median [Interquartile interval])
> note(Mean <Range interval>)
```

Table 1. Location and interval.

|  | Summary $n=74$ |
| :---: | :---: |
| Mileage (mpg) | 20.000 \{14.000; 29.000\} |
| Turn circle (ft.) | 40.000 [36.000; 43.000] |
| Trunk space (cu. ft.) | 13.757 <5.000; 23.000> |
| Median \{Interdecile interval\} |  |
| Median [Interquartile interval] |  |
| Mean <Range interval> |  |
| . collect style save (style from DTable sa | dtable-intervals <br> ved to file dtable-inter |

Now we can use this style and simply reference our composite results without having to redefine them.

```
. dtable, continuous(mpg, statistic(p50 idi))
> continuous(turn, statistic(q2 iqi))
> continuous(trunk, statistic(mean rangei))
> style(dtable-intervals)
```

Table 1. Location and interval.

|  | Summary <br> $\mathrm{n}=74$ |
| :--- | ---: |
| Mileage (mpg) | 20.000$\{14.000 ;$ $29.000\}$ <br> Turn circle (ft.) 40.000 <br> [36.000; $43.000]$ <br> Trunk space (cu. ft.) 13.757 <br>  $<5.000 ;$ $23.000>$ |
| Median \{Interdecile interval\} |  |
| Median [Interquartile interval] |  |
| Mean <Range interval> |  |

## The default style

Most of dtable's option defaults are controllable in its collection style. The following options are not part of dtable's collection style:

```
svy
subpop()
export()
name()
replace
label()
style()
warn
```

When the by () option is not specified, the default column() header options are

```
summary("Summary", nohide
    halign(center)
    font(, nobold
        noitalic
        nostrikeout
        nounderline)
    smcl(text))
```

When a variable is specified in the by () option, its default options are

```
notest
testnotes
totals
nomissing
```

and its default column() header options are

```
by(label, nohide
    fvlabel
    halign(center)
    font(, nobold
        noitalic
        nostrikeout
        nounderline)
    smcl(text))
total("Total", nohide
            halign(center)
            font(, nobold
                noitalic
                        nostrikeout
                    nounderline)
            smcl(text))
test("Test", nohide
        halign(center)
        font(, nobold
                        noitalic
                nostrikeout
                nounderline)
        smcl(text))
```

The default sample frequency title is " N ". When weights are not specified, the default sample frequency statistic is frequency; otherwise, sumw is reported. When the by () option is specified, percent is added to the default sample frequency statistic. The other default sample() options are

```
font(, nobold
    noitalic
    nostrikeout
    nounderline)
smcl(text)
place(items)
```

The defaults for the continuous() option are

```
statistic(mean sd)
test(regress)
font(, nobold
    noitalic
    nostrikeout
    nounderline)
smcl(text)
```

The defaults for the factor() option are

```
statistic(fvfrequency fvpercent)
test(pearson)
font(, nobold
    noitalic
    nostrikeout
    nounderline)
smcl(text)
```

There are no predefined composite results in dtable's default style.
The default formats are

```
nformat("%21.3fc", basestyle)
nformat("%21.Ofc" N count sumw frequency fvfrequency fvrawfrequency)
nformat("%9.1fc" percent rawpercent fvpercent fvrawpercent)
sformat("(%s%%)" percent rawpercent fvpercent fvrawpercent)
sformat("(%s)" sd)
nformat("%6.3f" regress poisson lnormal kwallis kwallis_ties pearson
    fisher lrchi2 svylr svywald svyllwald)
```

There is no default table title. The defaults for the titlestyles() option are

```
font(, nobold
    noitalic
    nostrikeout
    nounderline)
smcl(text)
```

## Methods and formulas

See Methods and formulas in [R] table for details on the statistics supported by dtable. When the svy or subpop() option is specified, the weights from svyset are used to compute statistics that support weights. In addition, the subpopulation variance $\widehat{\sigma}^{2}$ is computed as

$$
\widehat{\sigma}^{2}=s^{2} \frac{M}{n-1} \cdot \frac{n_{s}-1}{M_{s}}
$$

where $s^{2}$ is the sample variance as documented in [R] table, $M$ is the estimated population size, $n$ is the full sample size, $M_{s}$ is the estimated subpopulation size, and $n_{s}$ is the subpopulation sample size. The subpopulation standard deviation is computed as $\widehat{\sigma}=\sqrt{\widehat{\sigma}^{2}}$ and coefficient of variation (cv) is computed as $\widehat{\sigma} / \bar{x}$.

Let y be a continuous variable and by (group, tests) be in effect. For test (regress), dtable reports the $p$-value from test [\#1] after

$$
\text { regress y i.group }[i f][\text { in }][\text { weight }]
$$

For test (poisson), dtable reports the $p$-value from test [\#1] after

```
poisson y i.group [if] [in] [weight]
```

For test (lnormal), dtable reports the $p$-value from test [\#1] after

```
gsem y <- i.group [if] [in] [weight], family(lognormal)
```

For test(kwallis) and test(kwallis_ties), dtable reports the $p$-values corresponding with the $\chi^{2}$ statistics reported by

```
kwallis y [if] [in], by(group)
```

When the svy or subpop() option is specified, the prefix
svy, subpop([varname] [if]) :
is used with regress, poisson, and gsem. For more details, see [R] test, [R] regress, $[R]$ poisson, [SEM] gsem, [R] kwallis, and [SVY] svy.

Let $f$ be a factor variable and by (group, tests) be in effect. For nonsurvey data, the factorvariable test across groups is performed using
tabulate f group $[i f][i n][$ weight $]$, opt
where opt is an option of tabulate corresponding with the specified test (ftest) using the following table:

| ftest | opt |
| :--- | :--- |
| pearson | chi2 |
| fisher | exact |
| lrchi2 | lrchi2 |
| gamma | gamma |
| kendall | taub |
| cramer | V |

For survey data, dtable reports the $p$-value from

```
svy, subpop([varname] [if]): tabulate f group [if] [in], opt
```

where opt is an option of svy: tabulate corresponding with the specified test (ftest) using the following table:

| ftest | opt |
| :--- | :--- |
| pearson | pearson |
| svylr | lr |
| svywald | wald |
| svyllwald | llwald |

pearson, fisher, lrchi2, svylr, svywald, and svyllwald report a $p$-value. gamma, kendall, and cramer report the computed measure of association. For more details, see [R] tabulate twoway and [SVY] svy: tabulate twoway.

## Title

dydx - Calculate numeric derivatives and integrals

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options for dydx | Options for integ | Remarks and examples | Stored results |
| Methods and formulas | Acknowledgment | Reference | Also see |

## Description

dydx and integ calculate derivatives and integrals of numeric "functions".

## Quick start

For variables y and x corresponding to function $y=f(x)$, compute $d y / d x$ using cubic splines and store result in dy
dydx y x, generate(dy)
Evaluate the integral of $f(x)$ using cubic splines
integ y x
Evaluate the integral using the trapezoidal rule
integ $\mathrm{y} x$, trapezoid
Same as above, and generate variable iy containing integral evaluated for each value of x integ $\mathrm{y} x$, trapezoid generate(iy)

## Menu

dydx
Data $>$ Create or change data $>$ Other variable-creation commands $>$ Calculate numerical derivatives

## integ

Data $>$ Create or change data $>$ Other variable-creation commands $>$ Calculate numeric integrals

## Syntax

Derivatives of numeric functions

```
dydx yvar xvar [if] [in], generate(newvar) [dydx_options]
```

Integrals of numeric functions
integ yvar xvar [if] [in] [, integ_options]
dydx_options Description
Main

* generate (newvar)
replace
double
store results in variable named newvar
overwrite the existing variable
store new variable as double
*generate (newvar) is required.
integ_options
Description
Main
trapezoid
generate(newvar)
replace
double
initial(\#)
use trapezoidal rule to compute integrals; default is cubic splines store results in variable named newvar
overwrite the existing variable
store new variable as double
initial value of integral; default is initial(0)
by and collect are allowed with dydx and integ; see [U] 11.1.10 Prefix commands.

## Options for dydx

$\qquad$ Main
generate (newvar) specifies that results be stored in a new variable. generate() is required. replace specifies that if an existing variable is specified for generate(), it should be overwritten. double specifies that the new variable in generate() be stored as double. If the double option is not specified, the variable is stored using the current type as set by set type, which is float by default.

## Options for integ

$\qquad$ Main
trapezoid requests that the trapezoidal rule [the sum of $\left(x_{i}-x_{i-1}\right)\left(y_{i}+y_{i-1}\right) / 2$ ] be used to compute integrals. The default is cubic splines, which give superior results for most smooth functions; for irregular functions, trapezoid may give better results. generate(newvar) specifies that results be stored in a new variable.
replace specifies that if an existing variable is specified for generate(), it should be overwritten. double specifies that the new variable in generate() be stored as double. If the double option is not specified, the variable is stored using the current type as set by set type.
initial (\#) specifies the initial condition for calculating definite integrals; see Methods and formulas below. The default is initial(0).

## Remarks and examples

dydx and integ lets you extend Stata's graphics capabilities beyond data analysis and into mathematics.

## > Example 1

We graph $y=e^{-x / 6} \sin (x)$ over the interval $[0,12.56]$ :

```
. range x 0 12.56 100
Number of observations (_N) was 0, now 100.
. generate y = exp(-x/6)*sin(x)
. label variable y "exp(-x/6)*sin(x)"
. twoway connected y x, connect(i) yline(0)
```

We estimate the derivative by using $d y d x$ and compute the relative difference between this estimate and the true derivative.
. dydx y x, gen(dy)
. generate dytrue $=\exp (-x / 6) *(\cos (x)-\sin (x) / 6)$
. generate error $=$ abs(dy - dytrue)/dytrue

The error is greatest at the endpoints, as we would expect. The error is approximately $0.5 \%$ at each endpoint, but the error quickly falls to less than $0.01 \%$.

```
. label variable error "Error in derivative estimate"
. twoway line error x, ylabel(0(.002).006)
```

We now estimate the integral by using integ:

```
. integ y x, gen(iy)
number of points = 100
integral = . }8531639
. generate iytrue = (36/37)*(1-\operatorname{exp}(-x/6)*(\operatorname{cos}(x)+\operatorname{sin}(x)/6))
. display iytrue[_N]
. }8531590
. display abs(r(integral) - iytrue[_N])/iytrue[_N]
5.811e-06
. generate diff = iy - iytrue
```

The relative difference between the estimate [stored in r(integral)] and the true value of the integral is about $6 \times 10^{-6}$. A graph of the absolute difference (diff) is shown below. Here error is cumulative. Again, most of the error is due to a relatively poorer fit near the endpoints.
. label variable diff "Error in integral estimate"
. twoway line diff x, ylabel(0(5.00e-06).00001)

## Stored results

dydx stores the following in $r()$ :
Macros
$\mathrm{r}(\mathrm{y}) \quad$ name of $y \mathrm{var}$
integ stores the following in $r()$ :
Scalars
$r$ (N_points) number of unique $x$ points
$r$ (integral) estimate of the integral

## Methods and formulas

Consider a set of data points, $\left(x_{1}, y_{1}\right), \ldots,\left(x_{n}, y_{n}\right)$, generated by a function $y=f(x)$. dydx and integ first fit these points with a cubic spline, which is then analytically differentiated (integrated) to give an approximation for the derivative (integral) of $f$.

The cubic spline (see, for example, Press et al. [2007]) consists of $n-1$ cubic polynomials $P_{i}(x)$, with the $i$ th one defined on the interval $\left[x_{i}, x_{i+1}\right]$,

$$
P_{i}(x)=y_{i} a_{i}(x)+y_{i+1} b_{i}(x)+y_{i}^{\prime \prime} c_{i}(x)+y_{i+1}^{\prime \prime} d_{i}(x)
$$

where

$$
\begin{array}{ll}
a_{i}(x)=\frac{x_{i+1}-x}{x_{i+1}-x_{i}} & b_{i}(x)=\frac{x-x_{i}}{x_{i+1}-x_{i}} \\
c_{i}(x)=\frac{1}{6}\left(x_{i+1}-x_{i}\right)^{2} a_{i}(x)\left[\left\{a_{i}(x)\right\}^{2}-1\right] & d_{i}(x)=\frac{1}{6}\left(x_{i+1}-x_{i}\right)^{2} b_{i}(x)\left[\left\{b_{i}(x)\right\}^{2}-1\right]
\end{array}
$$

and $y_{i}^{\prime \prime}$ and $y_{i+1}^{\prime \prime}$ are constants whose values will be determined as described below. The notation for these constants is justified because $P_{i}^{\prime \prime}\left(x_{i}\right)=y_{i}^{\prime \prime}$ and $P_{i}^{\prime \prime}\left(x_{i+1}\right)=y_{i+1}^{\prime \prime}$.

Because $a_{i}\left(x_{i}\right)=1, a_{i}\left(x_{i+1}\right)=0, b_{i}\left(x_{i}\right)=0$, and $b_{i}\left(x_{i+1}\right)=1$. Therefore, $P_{i}\left(x_{i}\right)=y_{i}$, and $P_{i}\left(x_{i+1}\right)=y_{i+1}$. Thus, the $P_{i}$ jointly define a function that is continuous at the interval boundaries. The first derivative should be continuous at the interval boundaries; that is,

$$
P_{i}^{\prime}\left(x_{i+1}\right)=P_{i+1}^{\prime}\left(x_{i+1}\right)
$$

The above $n-2$ equations (one equation for each point except the two endpoints) and the values of the first derivative at the endpoints, $P_{1}^{\prime}\left(x_{1}\right)$ and $P_{n-1}^{\prime}\left(x_{n}\right)$, determine the $n$ constants $y_{i}^{\prime \prime}$.

The value of the first derivative at an endpoint is set to the value of the derivative obtained by fitting a quadratic to the endpoint and the two adjacent points; namely, we use

$$
P_{1}^{\prime}\left(x_{1}\right)=\frac{y_{1}-y_{2}}{x_{1}-x_{2}}+\frac{y_{1}-y_{3}}{x_{1}-x_{3}}-\frac{y_{2}-y_{3}}{x_{2}-x_{3}}
$$

and a similar formula for the upper endpoint.
dydx approximates $f^{\prime}\left(x_{i}\right)$ by using $P_{i}^{\prime}\left(x_{i}\right)$.
integ approximates $F\left(x_{i}\right)=F\left(x_{1}\right)+\int_{x_{1}}^{x_{i}} f(x) d x$ by using

$$
I_{0}+\sum_{k=1}^{i-1} \int_{x_{k}}^{x_{k+1}} P_{k}(x) d x
$$

where $I_{0}$ (an estimate of $F\left(x_{1}\right)$ ) is the value specified by the initial(\#) option. If the trapezoid option is specified, integ approximates the integral by using the trapezoidal rule:

$$
I_{0}+\sum_{k=1}^{i-1} \frac{1}{2}\left(x_{k+1}-x_{k}\right)\left(y_{k+1}+y_{k}\right)
$$

If there are ties among the $x_{i}$, the mean of $y_{i}$ is computed at each set of ties and the cubic spline is fit to these values.

## Acknowledgment

The present versions of dydx and integ were inspired by the dydx2 command written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model.

Maria Gaetana Agnesi (1718-1799) was an Italian mathematician and philosopher.
Born in Milan into a wealthy family, she was recognized as a child prodigy. At age nine, she published a detailed argument in Latin on the importance of education for women. At age 15, her father, a mathematics professor at the University of Bologna, presented her talents in language and philosophical reasoning to Bologna's intellectual elite. Uncomfortable with public life, she educated her twenty siblings and published on mathematics. After her father's death in 1752, she studied theology and devoted the rest of her life to helping the poor, homeless, and sick.

Agnesi's best known work, Instituzioni analitiche ad uso della gioventù italiana (Analytical Institutions for the Use of Italian Youth), written in 1748, helped develop the analysis of finite quantities and infinitesimals. At the time, it was hailed as the best introduction to calculus. The work also discussed an asymptotic curve that, because of mistranslation, would come to be known as the "Witch of Agnesi". In 1750, Pope Benedict XIV appointed her to the chair of mathematics and natural philosophy at Bologna, though she never served.

In addition to being recognized as an important mathematician, Agnesi is revered in the Basilica of San Nazaro in Milan. At her death, she was mourned by radical authors as a proponent for women's rights and by the Catholic faithful as a symbol of personal piety.

## Title

eform_option - Displaying exponentiated coefficients

## Description Remarks and examples Reference Also see

## Description

An eform_option causes the coefficient table to be displayed in exponentiated form: for each coefficient, $e^{b}$ rather than $b$ is displayed. Standard errors and confidence intervals (CIs) are also transformed.

An eform_option is one of the following:

| eform_option | Description |
| :--- | :--- |
| eform(string) | use string for the column title |
| eform | exponentiated coefficient, string is $\exp (b)$ |
| hr | hazard ratio, string is Haz . ratio |
| shr | subhazard ratio, string is SHR |
| $\underline{\mathrm{irr}}$ | incidence-rate ratio, string is IRR <br> or |
| $\underline{\mathrm{rrr}}$ | odds ratio, string is Odds ratio <br> relative-risk ratio, string is RRR |

## Remarks and examples

## > Example 1

Here is a simple example of the or option with svy: logit. The CI for the odds ratio is computed by transforming (by exponentiating) the endpoints of the CI for the corresponding coefficient.

```
. use https://www.stata-press.com/data/r18/nhanes2d
. svy, or: logit highbp female black
(running logit on estimation sample)
    (output omitted)
```

| highbp | Odds ratioLinearized <br> std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |  |
| ---: | ---: | ---: | :---: | :---: | ---: | ---: |
| female | .6107011 | .0326159 | -9.23 | 0.000 | .5476753 | .6809798 |
| black | 1.384865 | .1336054 | 3.37 | 0.002 | 1.137507 | 1.686011 |
| _cons | .7249332 | .0551062 | -4.23 | 0.000 | .6208222 | .8465035 |

Note: _cons estimates baseline odds.
We also could have specified the following command and received the same results as above:

## Title

eivreg - Errors-in-variables regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

eivreg fits errors-in-variables regression models when one or more of the independent variables are measured with error. To use eivreg, you must have an estimate of each independent variable's reliability or assume it is measured without error.

## Quick start

Regression of y on x 1 , x 2 , and x 3 adjusted for x 1 measured with $90 \%$ reliability eivreg y x1 x2 x3, reliab(x1 .9)

Same as above, but also specify $80 \%$ reliability for x 2

```
    eivreg y x1 x2 x3, reliab(x1 .9 x2 .8)
```

## Menu

Statistics $>$ Linear models and related $>$ Errors-in-variables regression

## Syntax

eivreg depvar $[$ indepvars $][$ if $][$ in $][$ weight $][$, options $]$
options Description
Model
reliab(indepvar \# [indepvar \# [...] ])
specify measurement reliability for each indepvar measured with error
Reporting
level(\#)
display_options
coeflegend
set confidence level; default is level (95)
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
display legend instead of statistics
indepvars may contain factor variables; see [U] 11.4.3 Factor variables. bootstrap, by, collect, jackknife, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
aweights are not allowed with the jackknife prefix; see [R] jackknife.
aweights and fweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

$\qquad$ Model
reliab (indepvar \# [indepvar \# [...]]) specifies the measurement reliability for each independent variable measured with error. Reliabilities are specified as pairs consisting of an independent variable name (a name that appears in indepvars) and the corresponding reliability $r, 0<r \leq 1$. Independent variables for which no reliability is specified are assumed to have reliability 1 . If the option is not specified, all variables are assumed to have reliability 1 , and the result is thus the same as that produced by regress (the ordinary least-squares results).

## Reporting

level(\#); see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\% fint), pformat (\% fint), sformat (\% fint), and nolstretch; see [R] Estimation options.

The following option is available with eivreg but is not shown in the dialog box:
coeflegend; see [R] Estimation options.

## Remarks and examples

For an introduction to errors-in-variables regression, see Draper and Smith (1998, 89-91) or Kmenta (1997, 352-357). Treiman (2009, 258-261) compares the results of errors-in-variables regression with conventional regression. Also see Lockwood and McCaffrey (2020) for how to use sem (see [SEM] sem) to fit errors-in-variables regression.

Errors-in-variables regression models are useful when one or more of the independent variables are measured with additive noise. Standard regression (as performed by regress) would underestimate the effect of the variable, and the other coefficients in the model can be biased to the extent that they are correlated with the poorly measured variable. You can adjust for the biases if you know the reliability:

$$
r=1-\frac{\text { noise variance }}{\text { total variance }}
$$

That is, given the model $\mathbf{y}=\mathbf{X} \boldsymbol{\beta}+\mathbf{u}$, for some variable $\mathbf{x}_{i}$ in $\mathbf{X}$, the $\mathbf{x}_{i}$ is observed with error, $\mathbf{x}_{i}=\mathbf{x}_{i}^{*}+\mathbf{e}$, and the noise variance is the variance of $\mathbf{e}$. The total variance is the variance of $\mathbf{x}_{i}$.

## > Example 1

Say that in our automobile data, the weight of cars was measured with error, and the reliability of our measured weight is 0.85 . The result of this would be to underestimate the effect of weight in a regression of, say, price on weight and foreign, and it would also bias the estimate of the coefficient on foreign (because being of foreign manufacture is correlated with the weight of cars). We would ignore all of this if we fit the model with regress:

| Source | SS | df | MS | Number of obs F (2, 71) <br> Prob > F <br> R-squared <br> Adj R-squared <br> Root MSE |  | 74 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Model | 316859273 | 2 | 158429637 |  |  | 0.0000 |
| Residual | 318206123 | 71 | 4481776.38 |  |  | 0.4989 |
| Total | 635065396 | 73 | 8699525.97 |  |  | $\begin{array}{r} 0.4848 \\ 2117 \end{array}$ |
| price | Coefficient | Std. err. | t | $P>\|t\|$ | [95\% conf. interval] |  |
| weight | 3.320737 | . 3958784 | 8.39 | 0.000 | 2.531378 | 4.110096 |
| foreign | 3637.001 | 668.583 | 5.44 | 0.000 | 2303.885 | 4970.118 |
| _cons | -4942.844 | 1345.591 | -3.67 | 0.000 | -7625.876 | -2259.812 |

With eivreg, we can account for our measurement error:

| . eivreg price weight foreign, reliab(weight .85) |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Variable | $\begin{array}{r} \text { Assumed } \\ \text { reliability } \end{array}$ |  |  |  |  |  |
|  |  |  |  | Number of | obs | 74 |
| weight | 0.85 |  |  | F ( 2 , | 71) | 18.46 |
| * | 1.00 |  |  | Prob > F |  | 0.0000 |
|  |  |  |  | R -squared |  | 0.6483 |
|  |  |  |  | Root MSE |  | 1773.54 |
| price | Coefficient | Std. err. | t | $P>\|t\|$ | [95\% conf | interval] |
| weight | 4.31985 | . 7134251 | 6.06 | 0.000 | 2.89732 | 5.742379 |
| foreign | 4637.32 | 849.0221 | 5.46 | 0.000 | 2944.418 | 6330.222 |
| _cons | -8257.017 | 2390.337 | -3.45 | 0.001 | -13023.21 | -3490.821 |

The effect of weight is increased - as we knew it would be-and here the effect of foreign manufacture is also increased. A priori, we knew only that the estimate of foreign might be biased; we did not know the direction.

## - Technical note

Swept under the rug in our example is how we would determine the reliability, $r$. We can easily see that a variable is measured with error, but we may not know the reliability because the ingredients for calculating $r$ depend on the unobserved noise.

For our example, we made up a value for $r$, and in fact we do not believe that weight is measured with error at all, so the reported eivreg results have no validity. The regress results were the statistically correct results here.

But let's say that we do suspect that weight is measured with error and that we do not know $r$. We could then experiment with various values of $r$ to describe the sensitivity of our estimates to possible error levels. We may not know $r$, but $r$ does have a simple interpretation, and we could probably produce a sensible range for $r$ by thinking about how the data were collected.

If the reliability, $r$, is less than the $R^{2}$ from a regression of the poorly measured variable on all the other variables, including the dependent variable, the information might as well not have been collected; no adjustment to the final results is possible. For our automobile data, running a regression of weight on foreign and price would result in an $R^{2}$ of 0.6743 . Thus, the reliability must be at least 0.6743 here. If we specify a reliability that is too small, eivreg will inform us and refuse to fit the model:

```
. eivreg price weight foreign, reliab(weight .6742)
reliability r() too small
r(399);
```

Returning to our problem of how to estimate $r$, too small or not, if the measurements are summaries of scaled items, the reliability may be estimated using the alpha command; see [MV] alpha. If the score is computed from factor analysis and the data are scored using predict's default options (see [MV] factor postestimation), the square of the standard deviation of the score is an estimate of the reliability.

## $>$ Example 2

Consider a model with more than one variable measured with error. For instance, say that our model is that price is a function of weight, foreign, and mpg and that both weight and mpg are measured with error.

```
. eivreg price weight foreign mpg, reliab(weight . }85\textrm{mpg . 95)
```

Errors-in-variables regression

e(properties)
e(predict)
e(marginsok)
e(asbalanced)
e(asobserved)
Matrices
e(b)
e(V)
Functions
e(sample) marks estimation sample

In addition to the above, the following is stored in r() :
Matrices
r(table)
matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

Let the model to be fit be

$$
\begin{aligned}
\mathbf{y} & =\mathbf{X}^{*} \boldsymbol{\beta}+\boldsymbol{\epsilon} \\
\mathbf{X} & =\mathbf{X}^{*}+\mathbf{U}
\end{aligned}
$$

where $\mathbf{X}^{*}$ are the true values and $\mathbf{X}$ are the observed values. $\boldsymbol{\epsilon}$ and $\mathbf{U}$ are assumed to be independent and have zero means and finite fourth moments. $\operatorname{Var}(\mathbf{U})$ is assumed to be diagonal.

Let $\mathbf{W}$ be the user-specified weights. If no weights are specified, $\mathbf{W}=\mathbf{I}$. If weights are specified, let $\mathbf{v}$ be the specified weights. If fweight frequency weights are specified, then $\mathbf{W}=\operatorname{diag}(\mathbf{v})$. If aweight analytic weights are specified, then $\mathbf{W}=\operatorname{diag}\left\{\mathbf{v} /\left(\mathbf{1}^{\prime} \mathbf{v}\right)\left(\mathbf{1}^{\prime} \mathbf{1}\right)\right\}$, meaning that the weights are normalized to sum to the number of observations.

The estimates bof $\boldsymbol{\beta}$ are obtained as $\mathbf{A}^{-1} \mathbf{X}^{\prime} \mathbf{W} \mathbf{y}$, where $\mathbf{A}=\mathbf{X}^{\prime} \mathbf{W} \mathbf{X}-\mathbf{S} . \mathbf{S}$ is a diagonal matrix with elements $\left(1-r_{j}\right) s_{j}^{2}$. Here $r_{j}$ is the user-specified reliability coefficient for the $j$ th explanatory variable (or 1 if not specified), and $s_{j}^{2}$ is the (appropriately weighted) sample variance of the variable.

The root mean squared error is $\left(\mathbf{y}^{\prime} \mathbf{W} \mathbf{y}-\mathbf{b A} \mathbf{b}^{\prime}\right) /(n-p)$, where $n$ is the number of observations and $p$ is the number of estimated parameters. The variance-covariance matrix of the estimators is obtained based on the formulas provided in Stefanski and Boos (2002), Buonaccorsi (2010), and Fuller (1987). For each $i=1,2, \ldots, n$, let residual $e_{i}=y_{i}-\mathbf{x}_{i} \mathbf{b}$, where $\mathbf{x}_{i}$ is the $i$ th row of $\mathbf{X}$. Consider matrix $\mathbf{H}$, where the $i$ th row of $\mathbf{H}, \mathbf{h}_{i}$, is

$$
\mathbf{h}_{i}^{\prime}=\left(\begin{array}{c}
e_{i} x_{i 1}+\left(x_{i 1}-\bar{x}_{1}\right)^{2}\left(1-r_{1}\right) b_{1} \\
e_{i} x_{i 2}+\left(x_{i 2}-\bar{x}_{2}\right)^{2}\left(1-r_{2}\right) b_{2} \\
\vdots \\
e_{i} x_{i p}+\left(x_{i p}-\bar{x}_{p}\right)^{2}\left(1-r_{p}\right) b_{p}
\end{array}\right)
$$

where $\bar{x}_{j}$ is the weighted mean of the $j$ th variable.
If analytic weights, aweights, are specified, the variance-covariance matrix is $\mathbf{A}^{-1}$ $\mathbf{H}^{\prime} \mathbf{W W H A}{ }^{-1}$; otherwise, it is $\mathbf{A}^{-1} \mathbf{H}^{\prime} \mathbf{W H A} \mathbf{H}^{-1}$.

## Postestimation commands

The following postestimation commands are available after eivreg:

| Command | Description |
| :--- | :--- |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estimates | cataloging estimation results <br> etable |
| lable of estimation results |  |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of <br> coefficients |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects <br> marginsplot <br> nlcom |
| preint estimates, standard errors, testing, and inference for nonlinear combinations |  |
| predict | of coefficients <br> pwcompare |
| linear predictions |  |
| pairwise comparisons of estimates |  |$\quad$| Wald tests of simple and composite linear hypotheses |
| :--- |
| testnl |$\quad$| Wald tests of nonlinear hypotheses |
| :--- |

## predict

## Description for predict

predict creates a new variable containing the linear prediction assuming that values of the covariates used for the prediction were measured without error.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

predict [type] newvar [if] [in]
Available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

## margins

## Description for margins

margins estimates margins of response for linear predictions.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

margins [marginlist] [, options]

## Remarks and examples

## > Example 1

We return to example 1 from [ R$]$ eivreg:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. eivreg price weight foreign, reliab(weight .85)
Errors-in-variables regression
```

| Variable | Assumed |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | reliability |  |  |  |  |
|  |  | Number of obs |  | $=$ | 74 |
| weight | 0.8500 | F ( 2 , | 71) | = | 18.46 |
| * | 1.0000 | Prob > F |  | = | 0.0000 |
|  |  | R-squared |  | = | 0.6483 |
|  |  | Root MSE |  | = | 1773.54 |

| price | Coefficient | Std. err. | t | P>\|t| | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | ---: | ---: |
| weight | 4.31985 | .7134251 | 6.06 | 0.000 | 2.89732 | 5.742379 |
| foreign | 4637.32 | 849.0221 | 5.46 | 0.000 | 2944.418 | 6330.222 |
| _cons | -8257.017 | 2390.337 | -3.45 | 0.001 | -13023.21 | -3490.821 |

We wish to predict the price of a foreign car that weighs 2,300 pounds. We can use predict because 2,300 pounds is the true weight, not the result of an error-prone measurement.

To make this prediction, first we add the new observation to the dataset.

```
. set obs 75
Number of observations (_N) was 74, now 75.
. replace foreign = 1 in 75
(1 real change made)
. replace weight = 2300 in 75
(1 real change made)
```

Now, we use predict to predict the price of the car.

```
. predict newprice in 75
(option xb assumed; fitted values)
(74 missing values generated)
(predictions assume covariates measured without error)
. list weight foreign newprice in 75
```

75. 

| weight | foreign | newprice |
| ---: | :--- | :--- |
| 2,300 | Foreign | 6315.957 |

predict issued a note reminding us that the computed predictions assume that the covariates used for prediction are measured without error. In general, you should avoid using predict to obtain in-sample predictions unless you first replace the measurement-error covariates with values that are error free.

## Description

ir is used with incidence-rate (incidence-density or person-time) data. It calculates point estimates and confidence intervals for the incidence-rate ratio (IRR) and incidence-rate difference (IRD), along with attributable or prevented fractions for the exposed and total population. iri is the immediate form of ir; see [U] 19 Immediate commands. Also see [R] poisson and [ST] stcox for related commands.
cs is used with cohort study data with equal follow-up time per subject and sometimes with crosssectional data. Risk is then the proportion of subjects who become cases. It calculates point estimates and confidence intervals for the risk difference, risk ratio, and (optionally) the odds ratio, along with attributable or prevented fractions for the exposed and total population. csi is the immediate form of cs; see [U] 19 Immediate commands. Also see [R] logistic for related commands.
cc is used with case-control and cross-sectional data. It calculates point estimates and confidence intervals for the odds ratio, along with attributable or prevented fractions for the exposed and total population. cci is the immediate form of cc; see [U] 19 Immediate commands. Also see [R] logistic for related commands.
tabodds is used with case-control and cross-sectional data. It tabulates the odds of failure against a categorical explanatory variable expvar. If expvar is specified, tabodds performs an approximate $\chi^{2}$ test of homogeneity of odds and a test for linear trend of the log odds against the numerical code used for the categories of expvar. Both tests are based on the score statistic and its variance; see Methods and formulas. When expvar is absent, the overall odds are reported. The variable $v a r_{\text {case }}$ is coded $0 / 1$ for individual and simple frequency records and equals the number of cases for binomial frequency records.

Optionally, tabodds tabulates adjusted or unadjusted odds ratios, using either the lowest levels of expvar or a user-defined level as the reference group. If adjust (varlist) is specified, it produces odds ratios adjusted for the variables in varlist along with a (score) test for trend.
mhodds is used with case-control and cross-sectional data. It estimates the ratio of the odds of failure for two categories of expvar, controlled for specified confounding variables, vars adjust , and tests whether this odds ratio is equal to one. When expvar has more than two categories but none are specified with the compare () option, mhodds assumes that expvar is a quantitative variable and calculates a 1-degree-of-freedom test for trend. It also calculates an approximate estimate of the log odds-ratio for a one-unit increase in expvar. This is a one-step Newton-Raphson approximation to the maximum likelihood estimate calculated as the ratio of the score statistic, $U$, to its variance, $V$ (Clayton and Hills 1993, 103).
mec is used with matched case-control data. It calculates McNemar's $\chi^{2}$; point estimates and confidence intervals for the difference, ratio, and relative difference of the proportion with the factor; and the odds ratio and its confidence interval. mcci is the immediate form of mcc; see [U] 19 Immediate commands. Also see $[R]$ clogit and $[R]$ symmetry for related commands.

## Quick start

## Cohort studies

IRR and IRD for the number of cases stored in cases for exposure indicator exposed given time exposed time
ir cases exposed time
Crude and Mantel-Haenszel combined IRRs with test of homogeneity for strata defined by svar
ir cases exposed time, by (svar)
Same as above, and standardize the IRR by weighting variable wvar1
ir cases exposed time, by (svar) standard(wvar1)
Same as above, but use person-time of the unexposed group as weights
ir cases exposed time, by (svar) estandard
IRR and IRD for 10 cases over 50 person-years in the exposed group and 15 cases over 100 person-years in the unexposed group
iri 101550100
Risk difference and ratio with binary indicators case and exposed using cumulative incidence data cs case exposed [fweight=wvar2]

Add odds ratios and calculate Fisher's exact $p$
cs case exposed [fweight=wvar2], or exact
Internally standardized risk ratio for strata defined by svar
cs case exposed [fweight=wvar2], by(svar) istandard
Risk difference and ratio for 12 cases and 55 noncases among exposed subjects and 16 cases and 125 noncases among unexposed subjects
csi 121655125

Case-control studies
Odds ratios from summary data with binary indicators case and exposed and frequency weight wvar3
cc case exposed [fweight=wvar3]
Same as above, but stratify analysis by svar and perform Breslow-Day and Tarone's homogeneity tests
cc case exposed [fweight=wvar3], by(svar) bd tarone
Odds ratios for 37 exposed cases, 148 unexposed cases, 7 exposed controls, and 137 unexposed controls
cci 371487137
Odds of binary event against catvar using summary data with frequency weight wvar4 tabodds event catvar [fweight=wvar4]

Same as above, but report odds ratios with the fourth level of catvar as the reference
tabodds event catvar [fweight=wvar4], or base(4)

Same as above, but tabulate Mantel-Haenszel adjusted odds ratios adjusting for values of categorical variable a
tabodds event catvar [fweight=wvar4], base(4) adjust(a)
Graph odds and confidence intervals against categories of catvar tabodds event catvar [fweight=wvar4], ciplot

Odds ratios for the effect of catvar on event controlling for categorical variable a using summary data with frequency weight wvar5
mhodds event catvar a [fweight=wvar5]
Same as above, but calculate odds ratios for each level of svar
mhodds event catvar a [fweight=wvar5], by (svar)
Maximum likelihood estimate of odds ratio for a equal to 4 compared with a equal to 1
mhodds event a [fweight=wvar5], compare $(4,1)$
Statistics on the difference in the proportion with the factor for exposed cases indicated in expcase and exposed controls indicated in expcontrol using summary data with frequency weight wvar6 mcc expcase expcontrol [fweight=wvar6]

Same as above, but indicate that there are 4 pairs where both cases and controls were exposed, 9 pairs where the case was exposed but the control was not, 3 pairs where the control was exposed but the case was not, and 14 pairs where neither subject was exposed

fweights are allowed; see [U] 11.1.6 weight.

## Options

Options are listed in the order that they appear in the syntax tables above. The commands for which the option is valid are indicated in parentheses immediately after the option name.

Options (ir, cs, cc, and mhodds)/Main (tabodds)
by (varname [, missing]) (ir, cs, cc, and mhodds) specifies that the tables be stratified on varname. Missing categories in varname are omitted from the stratified analysis, unless option missing is specified within by (). Within-stratum statistics are shown and then combined with Mantel-Haenszel weights. If estandard, istandard, or standard() is also specified (see below), the weights specified are used in place of Mantel-Haenszel weights.
estandard, istandard, and standard(varname) (ir, cs, and cc) request that within-stratum statistics be combined with external, internal, or user-specified weights to produce a standardized estimate. These options are mutually exclusive and can be used only when by () is also specified. (When by () is specified without one of these options, Mantel-Haenszel weights are used.)
estandard external weights are the person-time for the unexposed (ir), the total number of unexposed (cs), or the number of unexposed controls (cc).
istandard internal weights are the person-time for the exposed (ir), the total number of exposed (cs), or the number of exposed controls (cc). istandard can be used to produce, among other things, standardized mortality ratios (SMRs).
standard (varname) allows user-specified weights. varname must contain a constant within stratum and be nonnegative. The scale of varname is irrelevant.
pool (ir, cs, and cc) specifies that, in a stratified analysis, the directly pooled estimate also be displayed. The pooled estimate is a weighted average of the stratum-specific estimates using inverse-variance weights, which are the inverse of the variance of the stratum-specific estimate. pool is relevant only if by () is also specified.
nocrude (ir, cs, and cc) specifies that in a stratified analysis the crude estimate-an estimate obtained without regard to strata-not be displayed. nocrude is relevant only if by () is also specified.
nohom (ir, cs, and cc) specifies that a $\chi^{2}$ test of homogeneity not be included in the output of a stratified analysis. This tests whether the exposure effect is the same across strata and can be performed for any pooled estimate-directly pooled or Mantel-Haenszel. nohom is relevant only if by () is also specified.
ird (ir) may be used only with estandard, istandard, or standard(). It requests that ir calculate the standardized IRD rather than the default IRR.
midp (ir without by () and iri), the default, displays mid- $p$-adjusted $p$-values for one-sided and two-sided tests of IRD. The tests of IRD are not available with ir for stratified analysis, so midp is not allowed in combination with by (). Only one of exact or midp may be specified.
exact (ir without by() and iri) displays exact $p$-values for one-sided and two-sided tests of IRD instead of the default mid- $p$-adjusted $p$-values. This option produces $p$-values that are more conservative than the mid- $p$-adjusted $p$-values. When counts of exposed and unexposed cases are both large, exact and midp give similar results. The tests of IRD are not available with ir for stratified analysis, so exact is not allowed in combination with by (). Only one of exact or midp may be specified.
rd (cs) may be used only with estandard, istandard, or standard(). It requests that cs calculate the standardized risk difference rather than the default risk ratio.
bd (cc) specifies that Breslow and Day's $\chi^{2}$ test of homogeneity be included in the output of a stratified analysis. This tests whether the exposure effect is the same across strata. bd is relevant only if by () is also specified.
tarone (cc) specifies that Tarone's $\chi^{2}$ test of homogeneity, which is a correction to the Breslow-Day test, be included in the output of a stratified analysis. This tests whether the exposure effect is the same across strata. tarone is relevant only if by () is also specified.
binomial (varname) (cs, cc, tabodds, and mhodds) supplies the number of subjects (cases plus controls) for binomial frequency records. For individual and simple frequency records, this option is not used.
or (cs, csi, and tabodds), for cs and csi, reports the calculation of the odds ratio in addition to the risk ratio if by() is not specified. With by (), or specifies that a Mantel-Haenszel estimate of the combined odds ratio be made rather than the Mantel-Haenszel estimate of the risk ratio. In either case, this is the same calculation that would be made by cc and cci. Typically, cc, cci, or tabodds is preferred for calculating odds ratios. For tabodds, or specifies that odds ratios be produced; see base() for details about selecting a reference category. By default, tabodds will calculate odds.
adjust (varlist) (tabodds) specifies that odds ratios adjusted for the variables in varlist be calculated.
base(\#) (tabodds) specifies that the \#th category of expvar be used as the reference group for calculating odds ratios. If base () is not specified, the first category, corresponding to the minimum value of expvar, is used as the reference group.
cornfield (cc, cci, and tabodds) requests that the Cornfield (1956) approximation be used to calculate the confidence interval of the odds ratio. By default, cc and cci report an exact interval and tabodds reports a standard-error-based interval, with the standard error coming from the square root of the variance of the score statistic.
woolf (cs, csi, cc, cci, and tabodds) requests that the Woolf (1955) approximation, also known as the Taylor expansion, be used for calculating the standard error and confidence interval for the odds ratio. By default, cs and csi with the or option report the Cornfield (1956) interval; cc and cci report an exact interval; and tabodds reports a standard-error-based interval, with the standard error coming from the square root of the variance of the score statistic.
exact (cs, csi, cc, and cci) requests that Fisher's exact $p$ be calculated rather than the $\chi^{2}$ and its significance level. We recommend specifying exact whenever samples are small. When the least-frequent cell contains 1,000 cases or more, there will be no appreciable difference between the exact significance level and the significance level based on the $\chi^{2}$, but the exact significance level will take considerably longer to calculate. exact does not affect whether exact confidence intervals are calculated. Commands always calculate exact confidence intervals where they can, unless cornfield or woolf is specified.
compare ( $v_{1}, v_{2}$ ) (mhodds) indicates the categories of expvar to be compared; $v_{1}$ defines the numerator and $v_{2}$, the denominator. When compare() is not specified and there are only two categories, the second is compared with the first; when there are more than two categories, an approximate estimate of the odds ratio for a unit increase in expvar, controlled for specified confounding variables, is given.
level(\#) (ir, iri, cs, csi, cc, cci, tabodds, mhodds, mcc, and mcci) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [ $R$ ] level.

The following options are for use only with tabodds.
$\qquad$ Main
graph (tabodds) produces a graph of the odds against the numerical code used for the categories of expvar. All graph options except connect () are allowed. This option is not allowed with the or option or the adjust() option.
ciplot (tabodds) produces the same plot as the graph option, except that it also includes the confidence intervals. This option may not be used with either the or option or the adjust() option.
$\qquad$ Cl plot
ciopts(rcap_options) (tabodds) is allowed only with the ciplot option. It affects the rendition of the confidence bands; see [G-3] rcap_options.
$\qquad$ Plot
marker_options (tabodds) affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.
marker_label_options (tabodds) specify if and how the markers are to be labeled; see [G-3] marker_label_options.
cline_options (tabodds) affect whether lines connect the plotted points and the rendition of those lines; see [G-3] cline_options.

Add plots
addplot (plot) (tabodds) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

Y axis, X axis, Titles, Legend, Overall
twoway_options (tabodds) are any of the options documented in [G-3] twoway_options, excluding by (). These include options for titling the graph (see [G-3] title_options) and options for saving the graph to disk (see [G-3] saving_option).

## Remarks and examples

Remarks are presented under the following headings:

[^21]To calculate appropriate statistics and suppress inappropriate statistics, the ir, cs, cc, tabodds, mhodds, and mcc commands, along with their immediate counterparts, are organized in the way epidemiologists conceptualize data. ir processes incidence-rate data from prospective studies; cs, cohort study data with equal follow-up time (cumulative incidence); cc, tabodds, and mhodds, case-control or cross-sectional (prevalence) data; and mcc, matched case-control data. With the exception of mcc, these commands work with both simple and stratified tables.

Epidemiological data are often summarized in a contingency table from which various statistics are calculated. The rows of the table reflect cases and noncases or cases and person-time, and the columns reflect exposure to a risk factor. To an epidemiologist, cases and noncases refer to the outcomes of the process being studied. For instance, a case might be a person with cancer and a noncase might be a person without cancer.

A factor is something that might affect the chances of being ultimately designated a case or a noncase. Thus, a case might be a cancer patient, and the factor might be smoking behavior. A person is said to be exposed or unexposed to the factor. Exposure can be classified as a dichotomy, smokes or does not smoke, or as multiple levels, such as number of cigarettes smoked per week.

For an introduction to epidemiological methods, see Walker (1991). For an intermediate treatment, see Clayton and Hills (1993) and Schneider and Lilienfeld (2015). For other advanced discussions, see Kleinbaum, Kupper, and Morgenstern (1982) and Lash et al. (2021). For an analysis of incidence rates, see, for instance, Cummings (2019). For an anthology of writings on epidemiology since World War II, see Greenland (1987). See Jewell (2004) for a text aimed at graduate students in the medical professions that uses Stata for much of the analysis. See Dohoo, Martin, and Stryhn (2010) for a graduate-level text on the principles and methods of veterinary epidemiologic research; Stata datasets and do-files are available. Also see Dohoo, Martin, and Stryhn (2012) for a text that is a revision of their veterinary epidemiology text, but examples from human epidemiology are used.

## Incidence-rate data

In incidence-rate data from a prospective study, you observe the transformation of noncases into cases. Starting with a group of noncase subjects, you monitor them to determine whether they become cases (for example, stricken with cancer). You monitor two populations: those exposed and those unexposed to the factor (for example, multiple X-rays). A summary of the data is

|  | Exposed | Unexposed | Total |
| :--- | :---: | :---: | :---: |
| Cases | $a$ | $b$ | $a+b$ |
| Person-time | $N_{1}$ | $N_{0}$ | $N_{1}+N_{0}$ |

$>$ Example 1: iri
It will be easiest to understand these commands if we start with the immediate forms. Remember, in the immediate form, we specify the data on the command line rather than specifying names of variables containing the data; see [U] 19 Immediate commands. We have data (Boice and Monson [1977]; reported in Lash et al. [2021, 408]) on breast cancer cases and person-years of observation for women with tuberculosis repeatedly exposed to multiple X-ray fluoroscopies, and those not so exposed:

|  | X-ray fluoroscopy |  |
| :--- | ---: | ---: |
| Exposed | Unexposed |  |
| Breast cancer cases | 41 | 15 |
| Person-years | 28,010 | 19,017 |

Using iri, the immediate form of ir, we specify the values in the table following the command:

iri shows the table, reports the incidence rates for the exposed and unexposed populations, and then shows the point estimates of the difference and ratio of the two incidence rates along with their confidence intervals. The incidence rate is simply the frequency with which noncases are transformed into cases.

Next, iri reports the attributable fraction among the exposed (AFE), an estimate of the proportion of exposed cases attributable to exposure. We estimate that $46.1 \%$ of the 41 breast cancer cases among the exposed were due to exposure. (Had the IRR been less than 1, iri would have reported the prevented fraction among the exposed (PFE), an estimate of the net proportion of all potential cases in the exposed population that was prevented by exposure; see the following technical note.)

After that, the table shows the attributable fraction for the population (AFP), which is the net proportion of all cases attributable to exposure. This number, of course, depends on the proportion of cases that are exposed in the base population, which here is taken to be $41 / 56$ and may not be relevant in all situations. We estimate that $33.8 \%$ of the 56 cases were due to exposure. We estimate that 18.9 cases were caused by exposure; that is, $0.338 \times 56=0.461 \times 41=18.9$.

At the bottom of the table, iri reports one- and two-sided tests of the IRD. For the one-sided test of the number of exposed cases being 41 or greater, the $p$-value is 0.0177 . The two-sided test is twice the smallest one-sided $p$-value and is 0.0355 . These $p$-values are calculated using the mid- $p$ adjustment to exact $p$-values.

Exact $p$-values can be seen by specifying the exact option.

The exact $p$-values are slightly larger than those calculated using the mid- $p$ adjustment. This is always the case. However, when counts of exposed and unexposed cases are both large, they will be nearly identical. See Methods and formulas below.

## Technical note

When the IRR is less than 1, iri (and ir, cs, csi, cc, and cci) substitutes the prevented fraction for the attributable fraction. Let's reverse the roles of exposure in the above data, treating as exposed a person who did not receive the X-ray fluoroscopy. You can think of this as a new treatment for preventing breast cancer-the suggested treatment being not to use fluoroscopy.
. iri 15411901728010
Incidence-rate comparison

The PFE is the net proportion of all potential cases in the exposed population that were prevented by exposure. We estimate that $46.1 \%$ of potential cases among the women receiving the new "treatment" were prevented by the treatment. (Previously, we estimated that the same percentage of actual cases among women receiving the X-rays was caused by the X-rays.)

The prevented fraction for the population (PFP), which is the net proportion of all potential cases in the total population that was prevented by exposure, as with the attributable fraction, depends on the proportion of cases that are exposed in the base population - here taken as $15 / 56$-so it may not be relevant in all situations. We estimate that $18.6 \%$ of the potential cases were prevented by exposure.

See Greenland and Robins (1988) for a discussion of how to interpret attributable and prevented fractions.

## Example 2: ir

ir works like iri, except that it obtains the entries in the tables by summing data. You specify three variables: the first represents the number of cases represented by this observation, the second indicates whether the observation is for subjects exposed to the factor, and the third records the total time the subjects in this observation were observed. An observation may reflect one subject or a group of subjects.

For instance, here is a 2-observation dataset for the table in the previous example:
. use https://www.stata-press.com/data/r18/irxmpl
. list

|  | cases | exposed | time |
| :--- | ---: | ---: | ---: |
| 1. | 41 | 0 | 28010 |
| 2. | 15 | 19017 |  |

If we typed ir cases exposed time, we would obtain the same output that we obtained above. Another way the data might be recorded is

```
. use https://www.stata-press.com/data/r18/irxmpl2
```

. list

Here the first 2 observations will be automatically summed by ir because both are exposed. Finally, the data might be individual-level data:

```
. use https://www.stata-press.com/data/r18/irxmpl3
. list in 1/5
```

|  | cases | exposed | time |
| :--- | ---: | ---: | ---: |
| 1. | 1 | 1 | 10 |
| 2. | 0 | 1 | 8 |
| 3. | 0 | 0 | 9 |
| 4. | 1 | 0 | 2 |
| 5. | 0 | 1 | 1 |

The first observation represents a woman who got cancer, was exposed, and was observed for 10 years. The second is a woman who did not get cancer, was exposed, and was observed for 8 years, and so on.

## - Technical note

ir (and all the other commands) assumes that a subject was exposed if the exposed variable is nonzero and not missing, assumes the subject was not exposed if the variable is zero, and ignores the observation if the variable is missing. For ir, the case variable and the time variable are restricted to nonnegative integers and are summed within the exposed and unexposed groups to obtain the entries in the table.

## Stratified incidence-rate data

## Example 3: ir with stratified data

ir can work with stratified tables, as well as with single tables. For instance, Rothman (1986, 185) discusses data from Rothman and Monson (1973) on mortality by sex and age for patients with trigeminal neuralgia:

|  | Age through 64 |  | Age 65+ |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Males | Females | Males | Females |
| Deaths | 14 | 10 | 76 | 121 |
| Person-years | 1516 | 1701 | 949 | 2245 |

Entering the data into Stata, we have the following dataset:

```
. use https://www.stata-press.com/data/r18/rm
(Rothman and Monson 1973 data)
. list
```

| age | male | deaths | pyears |
| ---: | ---: | ---: | ---: |
| $<65$ | Male | 14 | 1516 |
| $<65$ | Female | 10 | 1701 |
| $65+$ | Male | 76 | 949 |
| $65+$ | Female | 121 | 2245 |

The stratified analysis of the IRR is

```
. ir deaths male pyears, by(age)
Stratified incidence-rate analysis
```

| Age category | IRR | [95\% conf. interval] | M-H weight |  |
| ---: | ---: | ---: | ---: | ---: |
| <65 | 1.570844 | .6489373 | 3.952809 | 4.712465 (exact) |
| $65+$ | 1.485862 | 1.100305 | 1.99584 | 35.95147 (exact) |
|  |  |  |  |  |
| Crude | 1.099794 | .831437 | 1.449306 |  |
| M-H combined | 1.49571 | 1.141183 | 1.960377 |  |

```
Test of homogeneity (M-H): chi2(1) = 0.02 Pr>chi2 = 0.8992
```

The row labeled $\mathrm{M}-\mathrm{H}$ combined reflects the combined Mantel-Haenszel estimates.
As with the previous example, it is not important that each entry in the table correspond to 1 observation in the data-ir sums the time (pyears) and case (deaths) variables within the exposure (male) category.

The difference between the unadjusted crude estimate and the Mantel-Haenszel estimate suggests confounding by age: women in the study are older, and older patients are more likely to die. But we should not use the Mantel-Haenszel estimate without checking its homogeneity assumption. The $\chi^{2}$ test of homogeneity gives a $p$-value of 0.8992 , so we have no evidence that the exposure effect (the effect of being male) differs across age categories. We are justified in using the Mantel-Haenszel estimate.

## - Technical note

Stratification is one way to deal with confounding; that is, perhaps sex affects the incidence of trigeminal neuralgia and so does age, so the table was stratified by age in an attempt to uncover the sex effect. (We are concerned that age may confound the true association between sex and the incidence of trigeminal neuralgia because the age distributions are so different for males and females. If age affects incidence, the difference in the age distributions would induce different incidences for males and females and thus confound the true effect of sex.)

We do not, however, have to use tables to uncover effects; the estimation alternative when we have aggregate data is Poisson regression, and we can use the same data on which we ran ir with poisson. Poisson regression also works with individual-level data.
(Although age in the previous example appears to be a string, it is actually a numeric variable taking on values 1 and 2 . We attached a value label to produce the labels <65 and $65+$ to make ir's output look better; see [U] 12.6.3 Value labels. Stata's estimation commands will ignore this labeling.)

```
. poisson deaths male age, exposure(pyears) irr
Iteration 0: Log likelihood = -10.836732
Iteration 1: Log likelihood = -10.734087
Iteration 2: Log likelihood = -10.733944
Iteration 3: Log likelihood = -10.733944
```

Poisson regression $\quad$ Number of obs $=\quad 4$
LR chi2(2) $=164.01$
Prob > chi2 $=0.0000$
Pseudo R2 $=0.8843$

Log likelihood = -10.733944

| Number of obs | $=4$ |
| :--- | :--- |
| LR chi2(2) | $=164.01$ |
| Prob > chi2 | $=0.0000$ |
| Pseudo R2 | $=0.8843$ |

| deaths | IRR | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | :---: | ---: |
| male | 1.495096 | .2060997 | 2.92 | 0.004 | 1.141118 | 1.95888 |
| age | 8.888775 | 1.934943 | 10.04 | 0.000 | 5.801616 | 13.61867 |
| _cons | .0006805 | .0002908 | -17.07 | 0.000 | .0002945 | .0015724 |
| ln(pyears) | 1 | (exposure) |  |  |  |  |

Note: _cons estimates baseline incidence rate.
Compare these results with the Mantel-Haenszel estimates produced by ir:

| Source | IRR | 95\% conf. interval |  |
| :--- | :---: | :---: | :---: |
| Mantel-Haenszel (ir) | 1.50 | 1.14 | 1.96 |
| poisson | 1.50 | 1.14 | 1.96 |

The results from poisson agree with the Mantel-Haenszel estimates to two decimal places. But poisson also estimates an IRR for age. Here the estimate is not of much interest, because the outcome variable is total mortality and we already knew that older people have a higher mortality rate. In other contexts, however, the estimate might be of greater interest.

See [R] poisson for an explanation of the poisson command.

## - Technical note

Both the model fit above and the preceding table asserted that exposure effects are the same across age categories and, if they are not, then both of the previous results are equally inappropriate. The table presented a test of homogeneity, reassuring us that the exposure effects do indeed appear to be constant. The Poisson-regression alternative can be used to reproduce that test by including interactions between the age groups and exposure:

```
. poisson deaths male age male#c.age, exposure(pyears) irr
Iteration 0: Log likelihood = -10.898799
Iteration 1: Log likelihood = -10.726225
Iteration 2: Log likelihood = -10.725904
Iteration 3: Log likelihood = -10.725904
```

Poisson regression
Log likelihood $=-10.725904$

| Number of obs | $=4$ |
| :--- | :--- | ---: |
| LR chi2(3) | $=164.03$ |
| Prob > chi2 | $=0.0000$ |
| Pseudo R2 | $=0.8843$ |

| deaths | IRR | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| male | 1.660688 | 1.396496 | 0.60 | 0.546 | .3195218 | 8.631283 |
| age | 9.167973 | 3.01659 | 6.73 | 0.000 | 4.810583 | 17.47226 |
| male\#c.age |  |  |  |  |  |  |
| Male | .9459 | .41539 | -0.13 | 0.899 | .3999832 | 2.236911 |
| _cons | .0006412 | .0004097 <br> (exposure) | -11.51 | 0.000 | .0001833 | .0022434 |

Note: _cons estimates baseline incidence rate.
The significance level of the male\#c.age effect is 0.899 , the same as previously reported by ir.
Here forming the male-times-age interaction was easy because there were only two age groups. Had there been more groups, the test would have been slightly more difficult-see the following technical note.

## - Technical note

A word of caution is in order when applying poisson (or any estimation technique) to more than two age categories. Say that in our data, we had three age categories, which we will call categories 0,1 , and 2 , and that they are stored in the variable agecat. We might think of the categories as corresponding to age less than $35,35-64$, and 65 and above.

With such data, we might type ir deaths male pyears, by (agecat), but we would not type poisson deaths male agecat, exposure(pyears) to obtain the equivalent Poisson-regression estimated results. Such a model might be reasonable, but it is not equivalent because we would be constraining the age effect in category 2 to be (multiplicatively) twice the effect in category 1.

To poisson (and all of Stata's estimation commands other than anova), agecat is simply one variable, and only one estimated coefficient is associated with it. Thus, the model is

$$
\text { Poisson index }=P=\beta_{0}+\beta_{1} \text { male }+\beta_{2} \text { agecat }
$$

The expected number of deaths is then $e^{P}$, and the IRR associated with a variable is $e^{\beta}$; see $[\mathrm{R}]$ poisson. Thus, the value of the Poisson index when male $==0$ and agecat $==1$ is $\beta_{0}+\beta_{2}$, and the possibilities are

|  | male $==0$ | mal $e==1$ |
| :--- | :---: | :---: |
| agecat $==0$ | $\beta_{0}$ | $\beta_{0}+\beta_{1}$ |
| agecat $==1$ | $\beta_{0}+\beta_{2}$ | $\beta_{0}+\beta_{2}+\beta_{1}$ |
| agecat $==2$ | $\beta_{0}+2 \beta_{2}$ | $\beta_{0}+2 \beta_{2}+\beta_{1}$ |

The age effect for agecat $=2$ is constrained to be twice the age effect for agecat $==1$ - the only difference between lines 3 and 2 of the table is that $\beta_{2}$ is replaced with $2 \beta_{2}$. Under certain circumstances, such a constraint might be reasonable, but it does not correspond to the assumptions made in generating the Mantel-Haenszel combined results.

To obtain results equivalent to the Mantel-Haenszel result, we must estimate a separate effect for each age group, meaning that we must replace $2 \beta_{2}$, the constrained effect, with $\beta_{3}$, a new coefficient that is free to take on any value. We can achieve this by creating two new variables and using them in place of agecat. agecat 1 will take on the value 1 when agecat is 1 and 0 otherwise; agecat 2 will take on the value 1 when agecat is 2 and 0 otherwise:

```
. generate agecat1 = (agecat==1)
. generate agecat2 = (agecat==2)
. poisson deaths male agecat1 agecat2 [fweight=pop], exposure(pyears) irr
```

In Stata, we do not have to generate these variables for ourselves. We could use factor variables:

```
. poisson deaths male i.agecat [fweight=pop], exposure(pyears) irr
```

See [U] 11.4.3 Factor variables.
To reproduce the homogeneity test with multiple age categories, we could type

```
. poisson deaths agecat##male [fweight=pop], exp(pyears) irr
. testparm agecat#male
```

Poisson regression combined with factor variables generalizes to multiway tables. Suppose that there are three exposure categories. Assume exposure variable burn takes on the values 1, 2, and 3 for first-, second-, and third-degree burns. The table itself is estimated by typing

```
. poisson deaths i.burn i.agecat [fweight=pop], exp(pyears) irr
```

and the test of homogeneity is estimated by typing
. poisson deaths burn\#\#agecat [fweight=pop], exp(pyears) irr
. testparm burn\#agecat

## Standardized estimates with stratified incidence-rate data

The by () option specifies that the data are stratified and, by default, will produce a Mantel-Haenszel combined estimate of the IRR. With the estandard, istandard, or standard(varname) options, you can specify your own weights and obtain standardized estimates of the IRR or IRD.
> Example 4: ir with stratified data, using standardized estimates
Lash et al. $(2021,417)$ report results from Doll and Hill (1966) on age-specific coronary disease deaths among British male doctors from cigarette smoking:

|  | Smokers |  | Nonsmokers |  |
| :--- | ---: | ---: | ---: | ---: |
| Age | Deaths | Person-years | Deaths | Person-years |
| $35-44$ | 32 | 52,407 | 2 | 18,790 |
| $45-54$ | 104 | 43,248 | 12 | 10,673 |
| $55-64$ | 206 | 28,612 | 28 | 5,710 |
| $65-74$ | 186 | 12,663 | 28 | 2,585 |
| $75-84$ | 102 | 5,317 | 31 | 1,462 |

We have entered these data into Stata:

```
. use https://www.stata-press.com/data/r18/dollhill3
(Doll and Hill (1966))
. list
```

|  | agecat | smokes | deaths | pyears |
| ---: | ---: | ---: | ---: | ---: |
| 1. | $35-44$ | 1 | 32 | 52,407 |
| 2. | $45-54$ | 1 | 104 | 43,248 |
| 3. | $55-64$ | 1 | 206 | 28,612 |
| 4. | $65-74$ | 1 | 186 | 12,663 |
| 5. | $75-84$ | 1 | 102 | 5,317 |
| 6. | $35-44$ | 0 | 2 | 18,790 |
| 7. | $45-54$ | 0 | 12 | 10,673 |
| 8. | $55-64$ | 0 | 28 | 5,710 |
| 9. | $65-74$ | 0 | 28 | 2,585 |
| 10. | $75-84$ | 0 | 31 | 1,462 |

We can obtain the Mantel-Haenszel combined estimate along with the crude estimate for ignoring stratification of the IRR and $90 \%$ confidence intervals by typing
. ir deaths smokes pyears, by(age) level(90)
Stratified incidence-rate analysis

| Age category | IRR | [90\% conf. interval] | M-H weight |  |
| ---: | ---: | ---: | ---: | ---: |
| $35-44$ | 5.736638 | 1.704271 | 33.61646 | 1.472169 (exact) |
| $45-54$ | 2.138812 | 1.274552 | 3.813282 | 9.624747 (exact) |
| $55-64$ | 1.46824 | 1.044915 | 2.110422 | 23.34176 (exact) |
| $65-74$ | 1.35606 | .9626026 | 1.953505 | 23.25315 (exact) |
| $75-84$ | .9047304 | .6375194 | 1.305412 | 24.31435 (exact) |
| Crude | 1.719823 | 1.437544 | 2.0688 |  |
| M-H combined | 1.424682 | 1.194375 | 1.699399 |  |

Test of homogeneity $(M-H): \operatorname{chi2}(4)=10.41 \quad \operatorname{Pr}>\operatorname{chi} 2=0.0340$
Note the presence of heterogeneity revealed by the test; the effect of smoking is not the same across age categories. Moreover, the listed stratum-specific estimates show an effect that appears to be declining with age. (Even if the test of homogeneity is not significant, you should always examine estimates carefully when stratum-specific effects occur on both sides of 1 for ratios and 0 for differences.)

Lash et al. $(2021,422)$ obtain the standardized IRR and $90 \%$ confidence intervals, weighting each age category by the population of the exposed group, thus producing the standardized mortality ratio (SMR). This calculation can be reproduced by specifying by (age) to indicate that the table is stratified and istandard to specify that we want the internally standardized rate. We may also specify that we would like to see the pooled estimate (weighted average where the weights are based on the variance of the strata calculations):
. ir deaths smokes pyears, by(age) level(90) istandard pool
Stratified incidence-rate analysis

| Age category | IRR | [90\% conf. interval] | Weight |  |
| ---: | ---: | :---: | ---: | ---: |
| $35-44$ | 5.736638 | 1.704271 | 33.61646 | 52407 (exact) |
| $45-54$ | 2.138812 | 1.274552 | 3.813282 | 43248 (exact) |
| $55-64$ | 1.46824 | 1.044915 | 2.110422 | 28612 (exact) |
| $65-74$ | 1.35606 | .9626026 | 1.953505 | 12663 (exact) |
| $75-84$ | .9047304 | .6375194 | 1.305412 | 5317 (exact) |
| Crude | 1.719823 | 1.437544 | 2.0688 |  |
| Pooled (direct) | 1.355343 | 1.134356 | 1.619382 |  |
| I. standardized | 1.417609 | 1.186541 | 1.693676 |  |
| Test of homogeneity (direct): chi2 (4) $=10.20$ | Pr>chi2 $=0.0372$ |  |  |  |

We obtained the simple pooled results because we specified the pool option. Note the significance of the homogeneity test; it provides the motivation for standardizing the rate ratios.

If we wanted the externally standardized ratio (weights proportional to the population of the unexposed group), we would substitute estandard for istandard in the above command.

We are not limited to IRRs; ir can also estimate IRDs. Differences may be standardized internally or externally. We will obtain the internally weighted difference (Lash et al. 2021, 418-419):
. ir deaths smokes pyears, by(age) level(90) istandard ird
Stratified incidence-rate analysis

| Age category | IRD | [90\% conf. interval] | Weight |  |
| ---: | ---: | ---: | ---: | ---: |
| $35-44$ | .0005042 | .0002877 | .0007206 | 52407 |
| $45-54$ | .0012804 | .0006205 | .0019403 | 43248 |
| $55-64$ | .0022961 | .0005628 | .0040294 | 28612 |
| $65-74$ | .0038567 | .0000521 | .0076614 | 12663 |
| $75-84$ | -.0020201 | -.0090201 | .00498 | 5317 |
| Crude | .0018537 | .001342 | .0023654 |  |
| I. standardized | .0013047 | .000712 | .0018974 |  |

## > Example 5: ir with user-specified weights

In addition to calculating results by using internal or external weights, ir (and cs and cc) can calculate results for arbitrary weights. If we wanted to obtain the IRR weighting each age category equally, we would type

```
. generate conswgt=1
. ir deaths smokes pyears, by(age) standard(conswgt)
Stratified incidence-rate analysis
```

| Age category | IRR | [95\% conf. interval] | Weight |  |
| ---: | ---: | ---: | ---: | ---: |
| $35-44$ | 5.736638 | 1.463557 | 49.40468 | 1 (exact) |
| $45-54$ | 2.138812 | 1.173714 | 4.272545 | 1 (exact) |
| $55-64$ | 1.46824 | .9863624 | 2.264107 | 1 (exact) |
| $65-74$ | 1.35606 | .9081925 | 2.096412 | 1 (exact) |
| $75-84$ | .9047304 | .6000757 | 1.399687 | 1 (exact) |
| Crude | 1.719823 | 1.391992 | 2.14353 |  |
| Standardized | 1.155026 | .9006199 | 1.481295 |  |

## - Technical note

estandard and istandard are convenience features; they do nothing different from what you could accomplish by creating the appropriate weights and using the standard() option. For instance, we could duplicate the previously shown results of istandard (example before last) by typing

```
. sort age smokes
. by age: generate wgt=pyears[_N]
. list in 1/4
```

|  | agecat | smokes | deaths | pyears | conswgt | wgt |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| 1. | $35-44$ | 0 | 2 | 18,790 | 1 | 52407 |
| 2. | $35-44$ | 1 | 32 | 52,407 | 1 | 52407 |
| 3. | $45-54$ | 0 | 12 | 10,673 | 1 | 43248 |
| 4. | $45-54$ | 1 | 104 | 43,248 | 1 | 43248 |

```
. ir deaths smokes pyears, by(age) level(90) standard(wgt) ird
    (output omitted)
```

sort age smokes made the exposed group (smokes $=1$ ) the last observation within each age category. by age: gen wgt=pyears [_N] created wgt equal to the last observation in each age category.

## Cumulative incidence data

Cumulative incidence data are "follow-up data with denominators consisting of persons rather than person-time" (Rothman 1986, 172). A group of noncases is monitored for some time, during which some become cases. Each subject is also known to be exposed or unexposed. A summary of the data is

|  | Exposed | Unexposed | Total |
| :--- | :---: | :---: | :---: |
| Cases | $a$ | $b$ | $a+b$ |
| Noncases | $c$ | $d$ | $c+d$ |
| Total | $a+c$ | $b+d$ | $a+b+c+d$ |

Data of this type are generally summarized using the risk ratio, $\{a /(a+c)\} /\{b /(b+d)\}$. A ratio of 2 means that an exposed subject is twice as likely to become a case than is an unexposed subject, a ratio of one-half means half as likely, and so on. The "null" value-the number corresponding to no effect-is a ratio of 1 . If cross-sectional data are analyzed in this format, the risk ratio becomes a prevalence ratio.

## Example 6: csi

We have data on diarrhea during a 10-day follow-up period among 30 breast-fed infants colonized with Vibrio cholerae 01 according to antilipopolysaccharide antibody titers in the mother's breast milk (Glass et al. [1983]; reported in Lash et al. [2021, 403]):

|  | Antibody level |  |
| :--- | ---: | ---: |
|  | High | Low |
| Diarrhea | 7 | 12 |
| No diarrhea | 9 | 2 |

The csi command works much like the iri command. Our sample is small, so we will specify the exact option.

|  | Exposed Unexposed | Total |  |
| :---: | :---: | :---: | :---: |
| Cases <br> Noncases | $\begin{array}{rr}7 & 12 \\ 9 & 2\end{array}$ | $\begin{aligned} & 19 \\ & 11 \end{aligned}$ |  |
| Total <br> Risk | 16 14 <br> .4375 .8571429 <br> Point estimate | $\begin{array}{r} 30 \\ .6333333 \\ {[95 \% \text { cor }} \end{array}$ | interval] |
| Risk difference <br> Risk ratio <br> Prev. frac. ex. <br> Prev. frac. pop | $\begin{array}{r} -.4196429 \\ .5104167 \\ .4895833 \\ .2611111 \end{array}$ | $\begin{array}{r} -.7240828 \\ .2814332 \\ .0742914 \end{array}$ | $\begin{array}{r} -.1152029 \\ .9257086 \\ .7185668 \end{array}$ |
| $\begin{aligned} & \text { 1-sided Fisher's exact } P=0.0212 \\ & \text { 2-sided Fisher's exact } P=0.0259 \end{aligned}$ |  |  |  |

We find that high antibody levels reduce the risk of diarrhea (the risk falls from 0.86 to 0.44 ). The difference is just significant at the $2.59 \%$ two-sided level. (Had we not specified the exact option, a $\chi^{2}$ value and its significance level would have been reported in place of Fisher's exact $p$. The calculated $\chi^{2}$ two-sided significance level would have been 0.0173 , but this calculation is inferior for small samples.)

## - Technical note

By default, cs and csi do not report the odds ratio, but they will if you specify the or option. If you want odds ratios, however, use the cc or cci commands - the commands appropriate for case-control data-because cs and csi calculate the attributable (prevented) fraction with the risk ratio, even if you specify or:
. csi 71292 , or exact

## Technical note

As with iri and ir, csi and cs report the AFE, AFP, PFE, or PFP; see the discussion under Incidencerate data above. In example 6 , we estimated that $49 \%$ of potential cases in the exposed population were prevented by exposure. We also estimated that exposure accounted for a $26 \%$ reduction in cases over the entire population, but that is based on the exposure distribution of the (small) population $(16 / 30)$ and probably is of little interest.

Fleiss, Levin, and Paik (2003, 128) report infant mortality by birthweight for 72,730 live white births in 1974 in New York City:
. csi 618422459767093

|  | Exposed | Unexposed | Total |  |
| :---: | :---: | :---: | :---: | :---: |
| Cases | 618 | 422 | 1040 |  |
| Noncases | 4597 | 67093 | 71690 |  |
| Total | 5215 | 67515 | 72730 |  |
| Risk | . 1185043 | . 0062505 | . 0142995 |  |
|  | Point estimate |  | [95\% con | interval] |
| Risk difference | . 1122539 |  | . 1034617 | . 121046 |
| Risk ratio | 18.95929 |  | 16.80661 | 21.38769 |
| Attr. frac. ex. | . 9472554 |  | . 9404996 | . 9532441 |
| Attr. frac. pop | . 5628883 |  |  |  |

In these data, exposed means a premature baby (birthweight $\leq 2,500 \mathrm{~g}$ ), and a case is a baby who is dead at the end of one year. We find that being premature accounts for $94.7 \%$ of deaths among the premature population. We also estimate, paraphrasing from Fleiss, Levin, and Paik (2003, 128), that $56.3 \%$ of all white infant deaths in New York City in 1974 could have been prevented if prematurity had been eliminated. (Moreover, Fleiss, Levin, and Paik put a standard error on the AFP. The formula is given in Methods and formulas but is appropriate only for the population on which the estimates are based because other populations may have different probabilities of exposure.)
> Example 7: cs
cs works like csi, except that it obtains its information from the data. The data equivalent to typing csi 71292 are

```
. use https://www.stata-press.com/data/r18/csxmpl, clear
. list
```

We could then type cs case exp [fweight=pop]. If we had individual-level data, so that each observation reflected a patient and we had 30 observations, we would type cs case exp.

## Stratified cumulative incidence data

> Example 8: cs with stratified data
Lash et al. $(2021,419)$ reprint the following age-specific information for deaths from all causes for tolbutamide and placebo treatment groups (University Group Diabetes Program 1970):

|  | Age through 54 |  | Age 55 |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Tolbutamide above | Placebo | Tolbutamide | Placebo |
| Dead | 8 | 5 | 22 | 16 |
| Surviving | 98 | 115 | 76 | 69 |

The data corresponding to these results are

```
. use https://www.stata-press.com/data/r18/ugdp
(University Group Diabetes Program 1970)
. list
```

| age | case | exposed | pop |
| ---: | ---: | ---: | ---: |
| $<55$ | Surviving | Placebo | 115 |
| $<55$ | Surviving | Tolbutamide | 98 |
| $<55$ | Dead | Placebo | 5 |
| $<55$ | Dead | Tolbutamide | 8 |
| $55+$ | Surviving | Placebo | 69 |
| $55+$ | Surviving | Tolbutamide | 76 |
| $55+$ | Dead | Placebo | 16 |
| $55+$ | Dead | Tolbutamide | 22 |

The order of the observations is unimportant. If we were now to type cs case exposed [fweight=pop], we would obtain a summary for all the data, ignoring the stratification by age. To incorporate the stratification, we type

Mantel-Haenszel weights are appropriate when the risks may differ according to the strata but the risk ratio is believed to be the same (homogeneous across strata). Under these assumptions, Mantel-Haenszel weights are designed to use the information efficiently. They are not intended to measure a composite risk ratio when the within-stratum risk ratios differ. Then, we want a standardized ratio (see below).

The risk ratios above appear to differ markedly, but the confidence intervals are also broad because of the small sample sizes. The test of homogeneity shows that the differences can be attributed to chance; the use of the Mantel-Haenszel combined test is sensible.

## - Technical note

Stratified cumulative incidence tables are not the only way to control for confounding. Another way is logistic regression. However, logistic regression measures effects with odds ratios, not with risk ratios. So before we fit a logistic model, let's use cs to estimate the Mantel-Haenszel odds ratio:
. cs case exposed [fweight=pop], by(age) or

| Age category | Odds ratio | [95\% conf. interval] | M-H weight |  |
| ---: | ---: | ---: | ---: | ---: |
| $<55$ | 1.877551 | .6238165 | 5.637046 | 2.168142 (Cornfield) |
| $55+$ | 1.248355 | .6112772 | 2.547411 | 6.644809 (Cornfield) |
| Crude | 1.510673 | .8381198 | 2.722012 |  |
| M-H combined | 1.403149 | .7625152 | 2.582015 |  |

Test of homogeneity (M-H) chi2(1) $=0.347 \quad \operatorname{Pr}>\operatorname{chi2}=0.5556$
Test that combined odds ratio $=1$ :
Mantel-Haenszel chi2(1) = 1.19 $\operatorname{Pr}>\operatorname{chi2}=0.2750$

The Mantel-Haenszel odds ratio is 1.40 . It measures the association between death and treatment while adjusting for age. A more general way to adjust for age is logistic regression; the outcome variable is case, and it is explained by age and exposed. (As in the incidence-rate example, age may appear to be a string variable in our data-we listed the data in the previous example-but it is actually a numeric variable taking on values 0 and 1 with value labels disguising that fact; see [U] 12.6.3 Value labels.)

| Logistic regression | Number of obs | $=409$ |
| :---: | :---: | :---: |
|  | LR chi2(2) | $=22.47$ |
|  | Prob > chi2 | $=0.0000$ |
| Log likelihood = -142.6212 | Pseudo R2 | $=0.0730$ |

| case | Odds ratio | Std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | :---: | :---: |
| exposed | 1.404674 | .4374454 | 1.09 | 0.275 | .7629451 | 2.586175 |
| age | 4.216299 | 1.431519 | 4.24 | 0.000 | 2.167361 | 8.202223 |
| _cons | .0513818 | .0170762 | -8.93 | 0.000 | .0267868 | .0985593 |

Note: _cons estimates baseline odds.
Compare these results with the Mantel-Haenszel estimates obtained with cs:

| Source | Odds ratio | $95 \%$ conf. interval |  |
| :--- | ---: | :---: | :---: |
| Mantel-Haenszel (cs) | 1.40 | 0.76 | 2.58 |
| logistic | 1.40 | 0.76 | 2.59 |

They are virtually identical.
Logistic regression has advantages over the stratified-table approach. First, we obtained an estimate of the age effect: being 55 years or over significantly increases the odds of death. In addition to the point estimate, 4.22, we have a confidence interval for the effect: 2.17 to 8.20 .

A discrete effect at age 55 is not a plausible model of aging. It would be more reasonable to assume that a 54 -year-old patient has a higher probability of death, due merely to age, than does a 53 -year-old patient; a 53-year-old, a higher probability than a 52 -year-old patient; and so on. If we had the underlying data, where each patient's age is presumably known, we could include the actual age in the model and so better control for the age effect. This would improve our estimate of the effect of being exposed to tolbutamide.

See [R] logistic for an explanation of the logistic command. Also see the technical note in Stratified incidence-rate data concerning categorical variables, which applies to logistic regression as well as Poisson regression.

## Standardized estimates with stratified cumulative incidence data

As with ir, cs can produce standardized estimates, and the method is basically the same, although the options for which estimates are to be combined or standardized make it confusing. We showed above that cs can produce Mantel-Haenszel weighted estimates of the risk ratio (the default) or the odds ratio (obtained by specifying or). cs can also produce standardized estimates of the risk ratio (the default) or the risk difference (obtained by specifying rd).
> Example 9: cs with stratified data, using standardized estimates
To produce an estimate of the internally standardized risk ratio by using our age-specific data on deaths from all causes for tolbutamide and placebo treatment groups (example above), we type

| . cs case exposed [fweight=pop], by (age) istandard |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| Age category | Risk ratio | [95\% conf. interval] | Weight |  |
| $<55$ | 1.811321 | .6112044 | 5.367898 | 106 |
| $55+$ | 1.192602 | .6712664 | 2.11883 | 98 |
| Crude | 1.435574 | .8510221 | 2.421645 |  |
| I. Standardized | 1.312122 | .7889772 | 2.182147 |  |

We could obtain externally standardized estimates by substituting estandard for istandard.
To produce an estimate of the risk ratio weighting each age category equally, we could type

```
. generate wgt=1
```

. cs case exposed [fweight=pop], by(age) standard(wgt)

| Age category | Risk ratio | [95\% conf. interval] | Weight |  |
| ---: | ---: | ---: | ---: | ---: |
| $<55$ | 1.811321 | .6112044 | 5.367898 | 1 |
| $55+$ | 1.192602 | .6712664 | 2.11883 | 1 |
| Crude | 1.435574 | .8510221 | 2.421645 |  |
| Standardized | 1.304737 | .7844994 | 2.169967 |  |

If we instead wanted the risk difference, we would type
. cs case exposed [fweight=pop], by(age) standard(wgt) rd

| Age category | Risk diff. | [95\% conf. interval] | Weight |  |
| ---: | ---: | ---: | ---: | ---: |
| $<55$ | .033805 | -.0278954 | .0955055 | 1 |
| $55+$ | .0362545 | -.0809204 | .1534294 | 1 |
| Crude | .0446198 | -.0192936 | .1085332 |  |
| Standardized | .0350298 | -.0311837 | .1012432 |  |

If we wanted to weight the less-than-55 age group five times as heavily as the 55 -and-over group, we would create wgt to contain 5 for the first age group and 1 for the second (or 10 for the first group and 2 for the second-the scale of the weights does not matter).

## Case-control data

In case-control data, you select a sample on the basis of the outcome under study; that is, cases and noncases are sampled at different rates. If you were examining the link between coffee consumption and heart attacks, for instance, you could select a sample of subjects with and without the heart problem and then examine their coffee-drinking behavior. A subject who has suffered a heart attack is called a case just as with cohort study data. A subject who has never suffered a heart attack, however, is called a control rather than merely a noncase, emphasizing that the sampling was performed with respect to the outcome.

In case-control data, all hope of identifying the risk (that is, incidence) of the outcome (heart attacks) associated with the factor (coffee drinking) vanishes, at least without information on the underlying sampling fractions, but you can examine the proportion of coffee drinkers among the two populations and reason that, if there is a difference, coffee drinking may be associated with the risk of heart attacks. Remarkably, even without the underlying sampling fractions, you can also measure the ratio of the odds of heart attacks if a subject drinks coffee to the odds if a subject does not-the so-called odds ratio.

What is lost is the ability to compare absolute rates, which is not always the same as comparing relative rates; see Fleiss, Levin, and Paik (2003, 123).

## > Example 10: cci

cci calculates the odds ratio and the attributable risk associated with a $2 \times 2$ table. Rothman et al. (1979; reprinted in Rothman [1986, 161], and Lash et al. [2021, 411]) present case-control data on the history of chlordiazopoxide use in early pregnancy for mothers of children born with and without congenital heart defects:

| Chlordiazopoxide use |  |  |
| :--- | ---: | ---: |
|  | Yes | No |
| Case mothers | 4 | 386 |
| Control mothers | 4 | 1250 |

. cci 43864 1250, level(90)

|  | Exposed | Unexposed | Total | Proportion exposed |
| :---: | :---: | :---: | :---: | :---: |
| Cases | 4 | 386 | 390 | 0.0103 |
| Controls | 4 | 1250 | 1254 | 0.0032 |
| Total |  | 1636 | 1644 | 0.0049 |
|  | Point estimate |  | [90\% conf | interval] |
| Odds ratio | 3.238342 |  | . 7698467 | 13.59664 |
| Attr. frac. ex. | . 6912 |  | -. 2989599 | . 9264524 |
| Attr. frac. pop | . 0070892 |  |  |  |

We obtain a point estimate of the odds ratio as 3.24 and a $\chi^{2}$ value, which is a test that the odds ratio is 1 , significant at the $10 \%$ level.

## - Technical note

The epitab commands can calculate three different confidence intervals for the odds ratio: the exact, Woolf, and Cornfield intervals. The exact interval, illustrated in example 10, is the default. The interval is "exact" because it uses an exact sampling distribution-a distribution with no unknown parameters under the null hypothesis. An exact interval does not use a normal or $\chi^{2}$ approximation. "Exact" does not describe the coverage probability; the coverage probability of a $90 \%$ exact interval is not exactly $90 \%$. The coverage probability is actually bounded below by $90 \%$ (Agresti 2013, 606), so a $90 \%$ exact interval will always cover the odds ratio with probability at least $90 \%$ (if the model is correct).

The Woolf and Cornfield intervals, on the other hand, are approximate. They approximate the exact sampling distribution with a normal model and are not guaranteed to maintain their nominal coverage: the coverage probability of a $90 \%$ approximate interval fluctuates above and below $90 \%$. The coverage approaches $90 \%$ only in the limit as the sample size increases. Exact intervals are conservative; approximate intervals can be conservative or anticonservative (Agresti 2013, 607).

If you wish to maintain nominal coverage, then you should use the exact interval. But you will pay a price for the coverage: the exact interval will usually be wider than the approximate intervals. Example 10 is no exception:

| Method | $90 \%$ | conf. interval | Command |
| :--- | :---: | :--- | :--- |
| exact | 0.77 | 13.60 | cci |
| Woolf | 1.01 | 10.40 | cci, woolf |
| Cornfield | 1.07 | 9.83 | cci, cornfield |

The exact interval is the widest of the three-so wide that it includes the null value of one-even though the $\chi^{2}$ test $p$-value of 0.0799 was significant at the $10 \%$ level. The exact interval and $\chi^{2}$ test come from different models, so we should not expect them to always agree on sharp conclusions such as statistical significance.

The odds-ratio intervals are all frequentist methods, so we cannot compare them rigorously with one example. See Brown (1981), Gart and Thomas (1982), and Agresti (1999) for more rigorous comparisons. Agresti (1999) found that the Woolf interval performed well, even for small samples.

Jerome Cornfield (1912-1979) was born in New York City. He majored in history at New York University and took courses in statistics at the US Department of Agriculture Graduate School but otherwise had little formal training. Cornfield held positions at the Bureau of Labor Statistics, the National Cancer Institute, the National Institutes of Health, Johns Hopkins University, the University of Pittsburgh, and George Washington University. He worked on many problems in biomedical statistics, including the analysis of clinical trials, epidemiology (especially case-control studies), and Bayesian approaches.

Barnet Woolf (1902-1983) was born in London. His parents were immigrants from Lithuania. Woolf was educated at Cambridge, where he studied physiology and biochemistry, and proposed methods for linearizing plots in enzyme chemistry that were later rediscovered by others (see Haldane [1957]). His later career in London, Birmingham, Rothamsted, and Edinburgh included lasting contributions to nutrition, epidemiology, public health, genetics, and statistics. He was also active in left-wing causes and penned humorous poems, songs, and revues.

## - Technical note

By default, cc and cci report exact confidence intervals but an approximate significance test. You can replace the approximate test with Fisher's exact test by specifying the exact option. We recommend specifying exact whenever any cell count is less than 1,000 .

```
. cci 4 3864 1250, exact level(90)
```

|  | Exposed | Unexposed | TotalProportion <br> exposed |
| ---: | ---: | ---: | ---: |
| Cases <br> Controls | 4 | 386 |  |
| Total | 4 | 1250 | 390 |

In this table, the one- and two-sided significance values are equal. This is not a mistake, but it does not happen often. Exact significance values are calculated by summing the probabilities for tables that have the same marginals (row and column sums) but that are less likely (given an odds ratio of 1) than the observed table. When considering each possible table, we might ask if the table is in the same or opposite tail as the observed table. If it is in the same tail, we would count the table under consideration in the one-sided test and, either way, we would count it in the two-sided test. Here all the tables more extreme than this table are in the same tail, so the one- and two-sided tests are the same.

The $p$-value of 0.0964 is significant at the $10 \%$ level, but the exact confidence interval is not (it includes the null odds ratio of one). It was not surprising that the exact interval disagreed with the $\chi^{2}$ test; after all, they come from different models. Now, the exact interval and Fisher's exact test also disagree, even though they come from the same model!

The test and interval disagree because the exact sampling distribution is asymmetric, and the test and interval handle the asymmetry differently. The two-sided test, as we have seen, sums the probabilities of all tables at least as unlikely as the observed table, and in example 10, all the unlikely tables fall in the same tail of the distribution. The other tail does not contribute to the $p$-value. The exact interval, on the other hand, must always use both tails of the distribution, because the interval inverts two one-sided tests, not one two-sided test (Breslow and Day 1980, 128-129).

## Technical note

The reported value of the AFE or PFE is calculated using the odds ratio as a proxy for the risk ratio. This can be justified only if the outcome is rare in the population. The extrapolation to the AFP or PFP assumes that the control group is a random sample of the corresponding group in the underlying population.
> Example 11: cc equivalent to cci
Equivalent to typing cci 438641250 would be typing cc case exposed [fweight=pop] with the following data:

```
. use https://www.stata-press.com/data/r18/ccxmpl, clear
. list
```

|  | case | exposed | pop |
| :--- | ---: | ---: | ---: |
| 1. | 1 | 1 | 4 |
| 2. | 1 | 0 | 386 |
| 3. | 0 | 1 | 4 |
| 4. | 0 | 0 | 1250 |

## Stratified case-control data

## Example 12: cc with stratified data

cc can work with stratified tables. Lash et al. $(2021,429)$ reprint and discuss data from a case-control study on infants with congenital heart disease and Down syndrome and healthy controls, according to maternal spermicide use before conception and maternal age at delivery (Rothman 1982):

|  | Maternal age to 34 |  | Maternal age 35+ |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
|  | Spermicide used | not used | Spermicide used | not used |
| Down syndrome | 3 | 9 | 1 | 3 |
| Controls | 104 | 1059 | 5 | 86 |

The data corresponding to these tables are

```
. use https://www.stata-press.com/data/r18/downs
(Congenital heart disease and Down syndrome)
. list
```

1. 

| case | exposed | pop | age |
| ---: | ---: | ---: | ---: |
| 1 | 1 | 3 | $<35$ |
| 1 | 0 | 9 | $<35$ |
| 0 | 1 | 104 | $<35$ |
| 0 | 0 | 1059 | $<35$ |
| 1 | 1 | 1 | $35+$ |
| 1 | 0 | 3 | $35+$ |
| 0 | 1 | 5 | $35+$ |
| 0 | 0 | 86 | $35+$ |

The stratified results for the odds ratio are

For no particular reason, we also specified the woolf option to obtain Woolf approximations to the within-stratum confidence intervals rather than the default. Had we wanted Tarone's test of homogeneity, we would have used

| Maternal age | Odds ratio | [95\% conf | interval] | M-H weight |
| :---: | :---: | :---: | :---: | :---: |
| <35 | 3.394231 | . 5812415 | 13.87412 | . 7965957 |
| 35+ | 5.733333 | . 0911619 | 85.89602 | . 1578947 |
| Crude | 3.501529 | . 8080857 | 11.78958 |  |
| M-H combined | 3.781172 | 1.18734 | 12.04142 |  |
| Test of homogeneity (M-H) <br> Test of homogeneity (Tarone) |  | $2(1)=$ | 0.14 Pr>c | i2 $=0.7105$ |
|  |  | $2(1)=$ | 0.14 Pr>c | i2 $=0.7092$ |
| Test that combined odds ratio $=1$ : |  |  |  |  |
| Mantel-Haenszel chi2(1) = 5.81 |  |  |  |  |
|  |  |  | Pr>chi2 | 0.0159 |

Whatever method you choose for calculating confidence intervals, Stata will report a test of homogeneity, which here is $\chi^{2}(1)=0.14$ and not significant. That is, the odds of Down syndrome might vary with maternal age, but we cannot reject the hypothesis that the association between Down syndrome and spermicide is the same in the two maternal age strata. This is thus a test to reject the appropriateness of the single, Mantel-Haenszel combined odds ratio-a rejection not justified by these data.

## Technical note

The cc command includes four tests of homogeneity: Mantel-Haenszel (the default); directly pooled, also known as the Woolf test (available with the pool option); Tarone (available with the tarone option); and Breslow-Day (available with the bd option). The preferred test is Tarone's (Tarone 1985, 94), which corrected an error in the Breslow-Day test; see Breslow (1996, 17-18) for details of the error and Tarone's correction.

The other two homogeneity tests, the Mantel-Haenszel and directly pooled, are less useful: they use the logs of the stratum-specific odds ratios, so they are undefined when any stratum has a zero cell. The epitab commands deal with the problem differently: cs omits the offending strata, while cc substitutes the Tarone test. The Tarone test does not use the stratum-specific odds ratios, so it can still be calculated when there are zero cells.

None of the tests is appropriate for finely stratified (many strata with only a few observations each) studies (Lash et al. 2021, 429). If you have fine stratification, one alternative is multilevel logistic regression; see [ME] melogit.

## - Technical note

As with cohort study data, an alternative to stratified tables for uncovering effects is logistic regression. From the logistic point of view, case-control data are no different from cohort study data-you must merely ignore the estimated intercept. The intercept is meaningless in case-control data because it reflects the baseline prevalence of the outcome, which you controlled by sampling.

The data we used with cc can be used directly by logistic. (The age variable, which appears to be a string, is really numeric with an associated value label; see [U] 12.6.3 Value labels. age takes on the value 0 for the age-less-than- 35 group and 1 for the $35+$ group.)

| . logistic case exposed age [fweight=pop] |  |
| :--- | :--- |
| Logistic regression | Number of obs $=1,270$ |
|  | LR chi2 2 ( $)$ |
|  | $=8.74$ |
| Log likelihood $=-81.517532$ | Prob $>$ chi2 $=0.0127$ |
|  | Pseudo R2 |

| case | Odds ratio | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | :--- | :---: | :---: | ---: | ---: |
| exposed | 3.787779 | 2.241922 | 2.25 | 0.024 | 1.187334 | 12.0836 |
| age | 4.582857 | 2.717352 | 2.57 | 0.010 | 1.433594 | 14.65029 |
| _cons | .0082631 | .0027325 | -14.50 | 0.000 | .0043218 | .0157988 |

Note: _cons estimates baseline odds.
We compare the results with those presented by cc in the previous example:

| Source | Odds ratio | $95 \%$ CI |  |
| :--- | ---: | :---: | :---: |
| Mantel-Haenszel (cc) | 3.78 | 1.19 | 12.04 |
| logistic | 3.79 | 1.19 | 12.08 |

As with the cohort study data in example 8 , results are virtually identical, and all the same comments we made previously apply once again.

To demonstrate an advantage of logistic regression, let's now ask a question that would be difficult to answer on the basis of a stratified table analysis. We now know that spermicide use appears to increase the risk of having a baby with Down syndrome, and we know that the mother's age also increases the risk. Is the effect of spermicide use statistically different for mothers in the two age groups?
. logistic case exposed age c.age\#exposed [fweight=pop]
Logistic regression
Log likelihood = -81.451332

Note: _cons estimates baseline odds.
The answer is no. The odds ratio and confidence interval reported for exposed now measure the spermicide effect for an age $==0$ (age $<35$ ) mother. The odds ratio and confidence interval reported for c.age\#exposed are the (multiplicative) difference in the spermicide odds ratio for an age==1 (age 35+) mother relative to a young mother. The point estimate is that the effect is larger for older mothers, suggesting grounds for future research, but the difference is not significant.

See $[R]$ logistic for an explanation of the logistic command. Also see the technical note under Incidence-rate data above concerning Poisson regression, which applies equally to logistic regression.

## Case-control data with multiple levels of exposure

In a case-control study, subjects with the disease of interest (cases) are compared with disease-free individuals (controls) to assess the relationship between exposure to one or more risk factors and disease incidence. Often exposure is measured qualitatively at several discrete levels or measured on a continuous scale and then grouped into three or more levels. The data can be summarized as

|  | Exposure level |  |  |  |  |
| :--- | :---: | :---: | :---: | ---: | :---: |
|  | 1 | 2 | $\ldots$ | $k$ | Total |
| Cases | $a_{1}$ | $a_{2}$ | $\ldots$ | $a_{k}$ | $M_{1}$ |
| Controls | $c_{1}$ | $c_{2}$ | $\ldots$ | $c_{k}$ | $M_{0}$ |
| Total | $N_{1}$ | $N_{2}$ | $\ldots$ | $N_{k}$ | $T$ |

An advantage afforded by having multiple levels of exposure is the ability to examine dose-response relationships. If the association between a risk factor and a disease or outcome is real, we expect the strength of that association to increase with the level and duration of exposure. A dose-response relationship provides strong support for a direct or even causal relationship between the risk factor and the outcome. On the other hand, the lack of a dose-response is usually seen as an argument against causality.

We can use the tabodds command to tabulate the odds of failure or odds ratios against a categorical exposure variable. The test for trend calculated by tabodds can serve as a test for dose-response if the exposure variable is at least ordinal. If the exposure variable has no natural ordering, the trend test is meaningless and should be ignored. See the technical note at the end of this section for more information regarding the test for trend.

Before looking at an example, consider three possible data arrangements for case-control and prevalence studies. The most common data arrangement is individual records, where each subject in the study has his or her own record. Closely related are frequency records where identical individual records are included only once, but with a variable giving the frequency with which the record occurs. The fweight weight option is used for these data to specify the frequency variable. Data can also be arranged as binomial frequency records where each record contains a variable, $D$, the number of cases; another variable, N, the number of total subjects (cases plus controls); and other variables. An advantage of binomial frequency records is that large datasets can be entered succinctly into a Stata database.

## Example 13: tabodds

Consider the following data from the Ille-et-Vilaine study of esophageal cancer, discussed in Breslow and Day (1980, chap. 4 and app. I), corresponding to subjects age 55-64 who use from 0 to 9 g of tobacco per day:

|  | Alcohol consumption (g/day) |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
|  | $0-39$ | $40-79$ | $80-119$ | $120+$ | Total |
| Cases | 2 | 9 | 9 | 5 | 25 |
| Controls | 47 | 31 | 9 | 5 | 92 |
| Total | 49 | 40 | 18 | 10 | 117 |

The study included 24 such tables, each representing one of four levels of tobacco use and one of six age categories. We can create a binomial frequency-record dataset by typing

| . input alcohol D N agegrp tobacco |  |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
| alcohol |  |  |  |  |  |
| a | D | N | agegrp | tobacco |  |
| 1. | 1 | 2 | 49 | 4 | 1 |
| 2. | 2 | 9 | 40 | 4 | 1 |
| 3. | 3 | 9 | 18 | 4 | 1 |
| 4. | 4 | 5 | 10 | 4 | 1 |
| 5. end |  |  |  |  |  |

where $D$ is the number of esophageal cancer cases and $N$ is the number of total subjects (cases plus controls) for each combination of six age groups (agegrp), four levels of alcohol consumption in $\mathrm{g} /$ day (alcohol), and four levels of tobacco use in $\mathrm{g} /$ day (tobacco).

Both the tabodds and mhodds commands can correctly handle all three data arrangements. Binomial frequency records require that the number of total subjects (cases plus controls) represented by each record $N$ be specified with the binomial () option.

We could also enter the data as frequency-weighted data:

| . input alcohol case freq agegrp |  |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
|  | alcohol | case | freq | agegrp | tobacco |
| 1. | 1 | 1 | 2 | 4 | 1 |
| 2. | 1 | 0 | 47 | 4 | 1 |
| 3. | 2 | 1 | 9 | 4 | 1 |
| 4. | 2 | 0 | 31 | 4 | 1 |
| 5. | 3 | 1 | 9 | 4 | 1 |
| 6. | 3 | 0 | 9 | 4 | 1 |
| 7. | 4 | 1 | 5 | 4 | 1 |
| 8. | 4 | 0 | 5 | 4 | 1 |
| 9. end |  |  |  |  |  |

If you are planning on using any of the other estimation commands, such as poisson or logistic, we recommend that you enter your data either as individual records or as frequency-weighted records and not as binomial frequency records, because the estimation commands currently do not recognize the binomial() option.

We have entered all the esophageal cancer data into Stata as a frequency-weighted record dataset as previously described. In our data, case indicates the esophageal cancer cases and controls, and freq is the number of subjects represented by each record (the weight).

We added value labels to the agegrp, alcohol, and tobacco variables in our dataset to ease interpretation in outputs, but these variables are numeric.

We are interested in the association between alcohol consumption and esophageal cancer. We first use tabodds to tabulate the odds of esophageal cancer against alcohol consumption:

```
. use https://www.stata-press.com/data/r18/bdesop, clear
(Ille-et-Vilaine study of esophageal cancer)
. tabodds case alcohol [fweight=freq]
```

| alcohol | Cases | Controls | Odds | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $0-39$ | 29 | 386 | 0.07513 | 0.05151 | 0.10957 |
| $40-79$ | 75 | 280 | 0.26786 | 0.20760 | 0.34560 |
| $80-119$ | 51 | 87 | 0.58621 | 0.41489 | 0.82826 |
| $120+$ | 45 | 22 | 2.04545 | 1.22843 | 3.40587 |

The test of homogeneity clearly indicates that the odds of esophageal cancer differ by level of alcohol consumption, and the test for trend indicates a significant increase in odds with increasing alcohol use. This suggests a strong dose-response relation. The graph option can be used to study the shape of the relationship of the odds with alcohol consumption. Most of the heterogeneity in these data can be "explained" by the linear increase in risk of esophageal cancer with increased dosage (alcohol consumption).

We also could have requested that the odds ratios at each level of alcohol consumption be calculated by specifying the or option. For example, tabodds case alcohol [fweight=freq], or would produce odds ratios using the minimum value of alcohol-that is, alcohol $=1$ ( $0-39$ ) -as the reference group, and the command tabodds case alcohol [fweight=freq], or base(2) would use alcohol $=2(40-79)$ as the reference group.

Although our results appear to provide strong evidence supporting an association between alcohol consumption and esophageal cancer, we need to be concerned with the possible existence of confounders, specifically age and tobacco use, in our data. We can again use tabodds to tabulate the odds of esophageal cancer against age and against tobacco use, independently:
. tabodds case agegrp [fweight=freq]

| agegrp | Cases | Controls | Odds | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $25-34$ | 1 | 115 | 0.00870 | 0.00121 | 0.06226 |
| $35-44$ | 9 | 190 | 0.04737 | 0.02427 | 0.09244 |
| $45-54$ | 46 | 167 | 0.27545 | 0.19875 | 0.38175 |
| $55-64$ | 76 | 166 | 0.45783 | 0.34899 | 0.60061 |
| $65-74$ | 55 | 106 | 0.51887 | 0.37463 | 0.71864 |
| $75+$ | 13 | 31 | 0.41935 | 0.21944 | 0.80138 |

. tabodds case tobacco [fweight=freq]

| tobacco | Cases | Controls | Odds | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $0-9$ | 78 | 447 | 0.17450 | 0.13719 | 0.22194 |
| $10-19$ | 58 | 178 | 0.32584 | 0.24228 | 0.43823 |
| $20-29$ | 33 | 99 | 0.33333 | 0.22479 | 0.49428 |
| $30+$ | 31 | 51 | 0.60784 | 0.38899 | 0.94983 |

Test of homogeneity (equal odds): chi2(3) = 29.33
$\operatorname{Pr}>\operatorname{chi} 2=0.0000$
Score test for trend of odds: chi2(1) = 26.93
$\operatorname{Pr}>\operatorname{chi} 2=0.0000$
We can see that there is evidence to support our concern that both age and tobacco use are potentially important confounders. Clearly, before we can make any statements regarding the association between esophageal cancer and alcohol use, we must examine and, if necessary, adjust for the effect of any confounder. We will return to this example in the following section.

## - Technical note

The score test for trend performs a test for linear trend of the log odds against the numerical code used for the exposure variable. The test depends not only on the relationship between dose level and the outcome but also on the numeric values assigned to each level or, to be more accurate, to the distance between the numeric values assigned. For example, the trend test on a dataset with four exposure levels coded $1,2,3$, and 4 gives the same results as coding the levels $10,20,30$, and 40 because the distance between the levels in each case is constant. In the first case, the distance is 1 unit, and in the second case, it is 10 units. However, if we code the exposure levels as 1,10 , 100 , and 1,000 , we would obtain different results because the distance between exposure levels is not constant. Thus, be careful when assigning values to exposure levels. You must determine whether equally spaced numbers make sense for your data or if other more meaningful values should be used.

Remember that we are testing whether a log-linear relationship exists between the odds and the exposure variable. For your particular problem, this relationship may not be correct or even make sense, so you must be careful in interpreting the output of this trend test.

## Case-control data with confounders and possibly multiple levels of exposure

In the esophageal cancer data example introduced earlier, we determined that the apparent association between alcohol consumption and esophageal cancer could be confounded by age and tobacco use. You can adjust for the effect of possible confounding factors by stratifying on these factors. This is the method used by both tabodds and mhodds to adjust for other variables in the dataset. We will compare and contrast these two commands in the following example.
> Example 14: tabodds, adjusting for confounding factors
We begin by using tabodds to tabulate unadjusted odds ratios.
. tabodds case alcohol [fweight=freq], or

| alcohol | Odds ratio |
| ---: | :--- |
| $0-39$ | 1.000000 |
| $40-79$ | 3.565271 |

The alcohol $=1$ group ( $0-39$ ) was used by tabodds as the reference category for calculating the odds ratios. We could have selected a different group by specifying the base() option; however, because the lowest dosage level is most often the appropriate reference group, as it is in these data, the base() option is seldom used.

We use tabodds with the adjust () option to tabulate Mantel-Haenszel age-adjusted odds ratios:
. tabodds case alcohol [fweight=freq], adjust(age)
Mantel-Haenszel odds ratios adjusted for agegrp

| alcohol | Odds ratio | chi2 | P>chi2 | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $0-39$ | 1.000000 |  |  |  |  |
| $40-79$ | 4.268155 | 37.36 | 0.0000 | 2.570025 | 7.088314 |
| $80-119$ | 8.018305 | 59.30 | 0.0000 | 4.266893 | 15.067922 |
| $120+$ | 28.570426 | 139.70 | 0.0000 | 12.146409 | 67.202514 |

We observe that the age-adjusted odds ratios are just slightly higher than the unadjusted ones, so it appears that age is not as strong a confounder as it first appeared. Even after adjusting for age, the dose-response relationship, as measured by the trend test, remains strong.

We now perform the same analysis but this time adjust for tobacco use instead of age.
. tabodds case alcohol [fweight=freq], adjust(tobacco)
Mantel-Haenszel odds ratios adjusted for tobacco

| alcohol | Odds ratio | chi2 | P>chi2 | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $0-39$ | 1.000000 | . |  |  |  |
| $40-79$ | 3.261178 | 28.53 | 0.0000 | 2.059764 | 5.163349 |
| $80-119$ | 6.771638 | 62.54 | 0.0000 | 3.908113 | 11.733306 |
| $120+$ | 19.919526 | 123.93 | 0.0000 | 9.443830 | 42.015528 |

Again we observe a significant dose-response relationship and not much difference between the adjusted and unadjusted odds ratios. We could also adjust for the joint effect of both age and tobacco use by specifying adjust (tobacco age), but we will not bother here.

A different approach to analyzing these data is to use the mhodds command. This command estimates the ratio of the odds of failure for two categories of an exposure variable, controlling for any specified confounding variables, and it tests whether this odds ratio is equal to one. For multiple exposures, if two exposure levels are not specified with compare (), then mhodds assumes that exposure is quantitative and calculates a 1-degree-of-freedom test for trend. This test for trend is the same one that tabodds reports.

## > Example 15: mhodds, controlling for confounding factors

We first use mhodds to estimate the effect of alcohol controlled for age:

```
. mhodds case alcohol agegrp [fweight=freq]
Score test for trend of odds with alcohol
    controlling for agegrp
```

| Odds ratio | chi2(1) | P>chi2 | $[95 \%$ conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: |
| 2.845895 | 135.09 | 0.0000 | 2.385749 | 3.394792 |

Note: The Odds ratio estimate is an approximation to the odds ratio for a one-unit increase in alcohol.

Because alcohol has more than two levels, mhodds estimates and reports an approximate ageadjusted odds ratio for a one-unit increase in alcohol consumption. The $\chi^{2}$ value reported is identical to that reported by tabodds for the score test for trend on the previous page.

We now use mhodds to estimate the effect of alcohol controlled for age, and while we are at it, we do this by levels of tobacco consumption:

```
. mhodds case alcohol agegrp [fweight=freq], by(tobacco)
Score test for trend of odds with alcohol
    controlling for agegrp
    by tobacco
```

| tobacco | Odds ratio | chi2(1) | P>chi2 | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $0-9$ | 3.579667 | 75.95 | 0.0000 | 2.68710 | 4.76871 |
| $10-19$ | 2.303580 | 25.77 | 0.0000 | 1.66913 | 3.17920 |
| $20-29$ | 2.364135 | 13.27 | 0.0003 | 1.48810 | 3.75589 |
| $30+$ | 2.217946 | 8.84 | 0.0029 | 1.31184 | 3.74992 |

Notes: Only 19 of the 24 strata formed in this analysis contribute information about the effect of the explanatory variable. The Odds ratio estimate is an approximation to the odds ratio for a one-unit increase in alcohol.
Mantel-Haenszel estimate controlling for agegrp and tobacco

| Odds ratio | chi2(1) | $\mathrm{P}>\mathrm{chi2}$ | [95\% conf. | interval] |
| :---: | :---: | :---: | :---: | :---: |
| 2.751236 | 118.37 | 0.0000 | 2.292705 | 3.301471 |
| Approximate test of homogeneity of odds ratios: |  |  | chi2(3) | 5.46 |
|  |  |  | Pr>chi2 | 0.1409 |

The first table reports estimates of the effect of alcohol for each level of tobacco use, controlling for age.

From the second table, we find that the effect of alcohol is about $\times 2.8$ when we control for both age and tobacco use. Again, because alcohol has more than two levels, mhodds estimates and reports an approximate Mantel-Haenszel age and tobacco-use adjusted odds ratio for a one-unit increase in alcohol consumption.

The $\chi^{2}$ test for trend reported with the Mantel-Haenszel estimate is again the same one that tabodds produces if adjust (agegrp tobacco) is specified.

To instead estimate the effect of tobacco use for each level of alcohol consumption, controlling for age, we type

```
. mhodds case tobacco agegrp [fweight=freq], by(alcohol)
Score test for trend of odds with tobacco
    controlling for agegrp
    by alcohol
```

| alcohol | Odds ratio | chi2(1) | P>chi2 | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $0-39$ | 2.420650 | 15.61 | 0.0001 | 1.56121 | 3.75320 |
| $40-79$ | 1.427713 | 5.75 | 0.0165 | 1.06717 | 1.91007 |
| $80-119$ | 1.472218 | 3.38 | 0.0659 | 0.97483 | 2.22339 |
| $120+$ | 1.214815 | 0.59 | 0.4432 | 0.73876 | 1.99763 |

Notes: Only 18 of the 24 strata formed in this analysis contribute information about the effect of the explanatory variable.
The Odds ratio estimate is an approximation to the odds ratio for a
one-unit increase in tobacco.
Mantel-Haenszel estimate controlling for agegrp and alcohol

| Odds ratio | chi2(1) | $\mathrm{P}>$ chi2 | [95\% conf | interval] |
| :---: | :---: | :---: | :---: | :---: |
| 1.553437 | 20.07 | 0.0000 | 1.281160 | 1.883580 |
| Approximate test of homogeneity of odds ratios: |  |  | $\begin{aligned} & \text { chi2 (3) } \\ & \text { Pr>chi2 } \end{aligned}$ | $\begin{array}{r} 5.26 \\ 0.1540 \end{array}$ |

From the second table, we find that the effect of tobacco, controlled for both age and alcohol consumption, is about $\times 1.6$.

Comparisons between particular levels of alcohol and tobacco consumption can be made by generating a new variable with levels corresponding to all combinations of alcohol and tobacco, as in

```
. egen alctob = group(alcohol tobacco)
. mhodds case alctob [fweight=freq], compare(16,1)
Maximum likelihood estimate of the odds ratio comparing alctob==16
    vs. alctob==1
\begin{tabular}{rrrr}
\hline Odds ratio & chi2(1) & P>chi2 & [95\% conf. interval] \\
\hline 93.333333 & 103.21 & 0.0000 & 14.766136589 .938431 \\
\hline
\end{tabular}
```

which yields an odds ratio of 93 between subjects with the highest levels of alcohol and tobacco and those with the lowest levels. Similar results can be obtained simultaneously for all levels of alctob using alctob $=1$ as the comparison group by specifying tabodds D alctob, binomial(N) or.

## Standardized estimates with stratified case-control data

## Example 16: cc with stratified data, using standardized estimates

You obtain standardized estimates (here for the odds ratio) by using cc just as you obtain standardized estimates by using ir or cs. Along with the by () option, you specify one of estandard, istandard, or standard(varname).

Case-control studies can provide standardized rate-ratio estimates when density sampling is used, or when the disease is rare (Lash et al. 2021, 422). Lash et al. (2021, 429) report the SMR for the case-control study on infants with congenital heart disease and Down syndrome. We can reproduce their estimates along with the pooled estimates by typing

| Maternal age | Odds ratio | [95\% conf | interval] | Weight |
| :---: | :---: | :---: | :---: | :---: |
| <35 | 3.394231 | . 5812415 | 13.87412 | 104 |
| 35+ | 5.733333 | . 0911619 | 85.89602 | 5 |
| Crude | 3.501529 | . 8080857 | 11.78958 |  |
| Pooled (direct) | 3.824166 | 1.196437 | 12.22316 |  |
| I. Standardized | 3.779749 | 1.180566 | 12.10141 |  |
| Test of homogeneity (direct) |  | chi2(1) = | 0.14 Pr>chi2 $=0.7109$ |  |

Using the distribution of the nonexposed subjects in the source population as the standard, we can obtain an estimate of the standardized rate ratio (SRR):
. cc case exposed [fweight=pop], by(age) estandard

| Maternal age | Odds ratio | [95\% conf. interval] | Weight |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $<35$ | 3.394231 | .5812415 | 13.87412 | 1059 (exact) |  |
| $35+$ | 5.733333 | .0911619 | 85.89602 | 86 (exact) |  |
|  |  |  |  |  |  |
| Crude | 3.501529 | .8080857 | 11.78958 |  | (exact) |
| E. Standardized | 3.979006 | 1.176096 | 13.46191 |  |  |

Finally, if we wanted to weight the two age groups equally, we could type

```
. generate wgt=1
```

. cc case exposed [fweight=pop], by(age) standard(wgt)

| Maternal age | Odds ratio | [95\% conf. interval] | Weight |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $<35$ | 3.394231 | .5812415 | 13.87412 | 1 (exact) |  |
| $35+$ | 5.733333 | .0911619 | 85.89602 | 1 (exact) |  |
| Crude | 3.501529 | .8080857 | 11.78958 |  |  |
| Standardized | 5.275104 | .6233794 | 44.6385 |  | (exact) |

## Matched case-control data

Matched case-control studies are performed to gain sample-size efficiency and to control for important confounding factors. In a matched case-control design, each case is matched with a control on the basis of demographic characteristics, clinical characteristics, etc. Thus, their difference with respect to the outcome must be due to something other than the matching variables. If the only difference between them was exposure to the factor, we could attribute any difference in outcome to the factor.

A summary of the data is

Controls

| Cases | Exposed | Unexposed | Total |
| :--- | :---: | :---: | :---: |
| Exposed | $a$ | $b$ | $M_{1}$ |
| Unexposed | $c$ | $d$ | $M_{0}$ |
| Total | $N_{1}$ | $N_{0}$ | $T=a+b+c+d$ |

Each entry in the table represents the number of case-control pairs. For instance, in $a$ of the pairs, both members were exposed; in $b$ of the pairs, the case was exposed but the control was not; and so on. In total, $T$ pairs were observed.
> Example 17: mcci
Rothman $(1986,257)$ discusses data from Jick et al. (1973) on a matched case-control study of myocardial infarction and drinking six or more cups of coffee per day (persons drinking from one to five cups per day were excluded):

Controls

| Cases | $6+$ cups | 0 cups |
| :--- | :---: | :---: |
| $6+$ cups | 8 | 8 |
| 0 cups | 3 | 8 |

mcci analyzes matched case-control data:
. mcci 8838

| Cases | Controls |  |  |
| ---: | ---: | ---: | ---: |
|  | Exposed | Unexposed | Total |
| Exposed | 8 | 8 | 16 |
| Unexposed | 3 | 8 | 11 |
| Total | 11 | 16 | 27 |

McNemar's chi2(1) = $2.27 \quad$ Prob $>$ chi2 $=0.1317$
Exact McNemar significance probability $\quad=0.2266$
Proportion with factor
Cases . 5925926
Controls . 4074074 [95\% conf. interval]
difference $.1851852-.0822542 \quad .4526246$
ratio 1.454545 . 8911012.374257
rel. diff. . $3125-.0243688$. 6493688
odds ratio 2.666667 . 640036415.6064 (exact)

The point estimate states that the odds of drinking 6 or more cups of coffee per day is 2.67 times greater among the myocardial infarction patients. The confidence interval is wide, however, and the $p$-value of 0.1317 from McNemar's test is not statistically significant.
mcc works like the other nonimmediate commands but does not handle stratified data. If you have stratified matched case-control data, you can use conditional logistic regression to estimate odds ratios; see [R] clogit.

Matched case-control studies can also be analyzed using mhodds by controlling on the variable used to identify the matched sets. For example, if the variable set is used to identify the matched set for each subject,

```
. mhodds fail xvar set
```

will do the job. Any attempt to control for further variables will restrict the analysis to the comparison of cases and matched controls that share the same values of these variables. In general, this would lead to the omission of many records from the analysis. Similar considerations usually apply when investigating effect modification by using the by () option. An important exception to this rule is that a variable used in matching cases to controls may appear in the by () option without loss of data.

## > Example 18: mhodds with matched case-control data

Let's use mhodds to analyze matched case-control studies using the study of endometrial cancer and exposure to estrogen described in Breslow and Day (1980, chap. 5). In this study, there are four controls matched to each case. Cases and controls are matched on age, marital status, and time living in the community. The data collected include information on the daily dose of conjugated estrogen therapy. Breslow and Day created four levels of the dose variable and began by analyzing the $1: 1$ study formed by using the first control in each set. We examine the effect of exposure to estrogen:

```
. mhodds fail est set
Mantel-Haenszel estimate of the odds ratio comparing est==1 vs.
    est==0
    controlling for set
```

| Odds ratio | chi2(1) | P>chi2 | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: |
| 9.666667 | 21.12 | 0.0000 |  | 2.944702 | $\mathbf{3 1 . 7 3 3 0 7 2}$

Note: Only 32 of the 63 strata formed in this analysis contribute information about the effect of the explanatory variable.

For the 1:1 matched study, the Mantel-Haenszel methods are equivalent to conditional likelihood methods. The maximum conditional likelihood estimate of the odds ratio is given by the ratio of the off-diagonal frequencies in the two-way (case-control) table below. The data must be in the 1-observation-per-group format; that is, the matched case and control must appear in 1 observation (the same format as required by the mcc command; see also [R] clogit).

```
. keep fail est set
. reshape wide est, i(set) j(fail)
(j = 0 1)
\begin{tabular}{lrll} 
Data & Long & \(\rightarrow>\) & Wide \\
\hline Number of observations & 126 & \(->\) & 63 \\
Number of variables & 3 & \(\rightarrow\) & 3 \\
j variable (2 values) & fail & \(\rightarrow\) & (dropped) \\
xij variables: & est & \(\rightarrow\) & est0 est1 \\
\hline
\end{tabular}
```

```
. rename est1 case
. rename estO control
. label variable case case
. label variable control control
```

. tabulate case control

| case | con 0 | 1 | Total |
| :---: | :---: | :---: | :---: |
| 0 | 4 | 3 | 7 |
| 1 | 29 | 27 | 56 |
| Total | 33 | 30 | 63 |

The odds ratio is $29 / 3=9.67$, which agrees with the value obtained from mhodds. In the more general 1: $m$ matched study, however, the Mantel-Haenszel methods are no longer equivalent to maximum conditional likelihood, although they are usually close.

To illustrate the use of the by () option in matched case-control studies, we look at the effect of exposure to estrogen, stratified by age3, which codes the sets into three age groups (55-64, 65-74, and 75+) as follows:

```
. use https://www.stata-press.com/data/r18/bdendo11, clear
(Endometrial cancer and estrogen exposure)
. generate age3 = agegrp
. recode age3 1/2=1 3/4=2 5/6=3
(124 changes made to age3)
. mhodds fail est set, by(age3)
Mantel-Haenszel estimate of the odds ratio comparing est==1 vs. est==0
    controlling for set
    by age3
```

| age3 | Odds ratio | chi2(1) | P>chi2 | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 6.000000 | 3.57 | 0.0588 | 0.72235 | 49.83724 |
| 2 | 15.000000 | 12.25 | 0.0005 | 1.98141 | 113.55557 |
| 3 | 8.000000 | 5.44 | 0.0196 | 1.00059 | 63.96252 |

Note: Only 32 of the 63 strata formed in this analysis contribute information about the effect of the explanatory variable.
Mantel-Haenszel estimate controlling for set and age3

| Odds ratio | chi2 (1) | P>chi2 | [95\% conf. interval] |  |
| ---: | :---: | :---: | ---: | ---: |
| 9.666667 | 21.12 | 0.0000 | 2.944702 | 31.733072 |
| Approximate test of homogeneity of odds ratios: chi2 (2) | $=$ | 0.41 |  |  |

There is no further loss of information when we stratify by age3 because age was one of the matching variables.

The full set of matched controls can be used in the same way. For example, the effect of exposure to estrogen is obtained (using the full dataset) with

```
. use https://www.stata-press.com/data/r18/bdendo, clear
(Endometrial cancer and estrogen exposure)
. mhodds fail est set
Mantel-Haenszel estimate of the odds ratio comparing est==1 vs.
    est==0
    controlling for set
```

| Odds ratio | chi2(1) | P>chi2 | $[95 \%$ conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: |
| 8.461538 | 31.16 | 0.0000 | 3.437773 | 20.826746 |

Note: Only 58 of the 63 strata formed in this analysis contribute information about the effect of the explanatory variable.

The effect of exposure to estrogen, stratified by age3, is obtained with

```
. generate age3 =agegrp
. recode age3 1/2=1 3/4=2 5/6=3
(310 changes made to age3)
. mhodds fail est set, by(age3)
Mantel-Haenszel estimate of the odds ratio comparing est==1 vs. est==0
    controlling for set
    by age3
```

| age3 | Odds ratio | chi2(1) | P>chi2 | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 3.800000 | 3.38 | 0.0660 | 0.82165 | 17.57438 |
| 2 | 10.666667 | 18.69 | 0.0000 | 2.78773 | 40.81376 |
| 3 | 13.500000 | 9.77 | 0.0018 | 1.59832 | 114.02620 |

Note: Only 58 of the 63 strata formed in this analysis contribute information about the effect of the explanatory variable.

Mantel-Haenszel estimate controlling for set and age3

| Odds ratio | chi2(1) | $\mathrm{P}>\mathrm{chi2}$ | [95\% conf. interval] |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 8.461538 | 31.16 | 0.0000 | 3.437773 |  | 20.82 | 26746 |
| pproximate test of homogeneity of odds ratios: chi2 2 ) $=1.41$ |  |  |  |  |  |  |

## Glossary

attributable fraction. An attributable fraction is the reduction in the risk of a disease or other condition of interest when a particular risk factor is removed.
case-control studies. In case-control studies, cases meeting a fixed criterion are matched to noncases ex post to study differences in possible covariates. Relative sample sizes are usually fixed at $1: 1$ or 1:2 but sometimes vary once the survey is complete. In any case, sample sizes do not reflect the distribution in the underlying population.
cohort studies. In cohort studies, a group that is well defined is monitored over time to track the transition of noncases to cases. Cohort studies differ from incidence studies in that they can be retrospective as well as prospective.
confounding. In the analysis of contingency tables, factor or interaction effects are said to be confounded when the effect of one factor is combined with that of another. For example, the effect of alcohol consumption on esophageal cancer may be confounded with the effects of age, smoking, or both. In the presence of confounding, it is often useful to stratify on the confounded factors that are not of primary interest, in the above example, age and smoking.
cross-sectional or prevalence studies. Cross-sectional studies sample distributions of healthy and diseased subjects in the population at one point in time.
crude estimate. A crude estimate has not been adjusted for the effects of other variables. Disregarding a stratification variable, for example, yields a crude estimate.
incidence and incidence rate. Incidence is the number of new failures (for example, number of new cases of a disease) that occur during a specified period in a population at risk (for example, of the disease).

Incidence rate is incidence divided by the sum of the length of time each individual was exposed to the risk.

Do not confuse incidence with prevalence. Prevalence is the fraction of a population that has the disease. Incidence refers to the rate at which people contract a disease, whereas prevalence is the total number actually sick at a given time.
incidence studies, longitudinal studies, and follow-up studies. Whichever word is used, these studies monitor a population for a time to track the transition of noncases into cases. Incidence studies are prospective. Also see cohort studies.
matched case-control study. Also known as a retrospective study, a matched case-control study is a study in which persons with positive outcomes are each matched with one or more persons with negative outcomes but with similar characteristics.
odds and odds ratio. The odds in favor of an event are $o=p /(1-p)$, where $p$ is the probability of the event. Thus if $p=0.2$, the odds are 0.25 , and if $p=0.8$, the odds are 4 .
The $\log$ of the odds is $\ln (o)=\operatorname{logit}(p)=\ln \{p /(1-p)\}$, and logistic-regression models, for instance, fit $\ln (o)$ as a linear function of the covariates.
The odds ratio is a ratio of two odds: $o_{1} / o_{0}$. The individual odds that appear in the ratio are usually for an experimental group and a control group, or two different demographic groups.
prevented fraction. A prevented fraction is the reduction in the risk of a disease or other condition of interest caused by including a protective risk factor or public-health intervention.
prospective study. Also known as a prospective longitudinal study, a prospective study is a study based on observations over the same subjects for a given period.
risk factor. This is a variable associated with an increased or decreased risk of failure.
risk ratio. In a log-linear model, this is the ratio of probability of survival associated with a one-unit increase in a risk factor relative to that calculated without such an increase, that is, $R(x+1) / R(x)$. Given the exponential form of the model, $R(x+1) / R(x)$ is constant and is given by the exponentiated coefficient.

SMR. See standardized mortality (morbidity) ratio.
standardized mortality (morbidity) ratio. Standardized mortality (morbidity) ratio (SMR) is the observed number of deaths divided by the expected number of deaths. It is calculated using indirect standardization: you take the population of the group of interest-say, by age, sex, and other factors-and calculate the expected number of deaths in each cell (expected being defined as the number of deaths that would have been observed if those in the cell had the same mortality
as some other population). You then take the ratio to compare the observed with the expected number of deaths. For instance,

|  | $(1)$ <br> Population <br> of group | Deaths per 100,000 <br> in general pop. | $(1) \times(2)$ <br> Expected \# <br> of deaths | $(4)$ <br> Observed <br> deaths |
| :--- | :---: | :---: | :---: | :---: |
| $25-34$ | 95,965 | 105.2 | 100.9 | 92 |
| $34-44$ | 78,280 | 203.6 | 159.4 | 180 |
| $44-54$ | 52,393 | 428.9 | 224.7 | 242 |
| $55-64$ | 28,914 | 964.6 | 278.9 | 312 |
| Total |  | 763.9 | 826 |  |
|  | SMR $=826 / 763.9=1.08$ |  |  |  |

stratified test. A stratified test is performed separately for each stratum. The stratum-specific results are then combined into an overall test statistic.

## Methods and formulas

The notation for incidence-rate data is

|  | Exposed | Unexposed | Total |
| :--- | :---: | :---: | :---: |
| Cases | $a$ | $b$ | $M_{1}$ |
| Person-time | $N_{1}$ | $N_{0}$ | $T$ |

The notation for $2 \times 2$ tables is

|  | Exposed | Unexposed | Total |
| :--- | :---: | :---: | :---: |
| Cases | $a$ | $b$ | $M_{1}$ |
| Controls | $c$ | $d$ | $M_{0}$ |
| Total | $N_{1}$ | $N_{0}$ | $T$ |

The notation for $2 \times k$ tables is

|  | Exposure level |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | $\ldots$ | k | Total |
| Cases | $a_{1}$ | $a_{2}$ | $\ldots$ | $a_{k}$ | $M_{1}$ |
| Controls | $c_{1}$ | $c_{2}$ | $\ldots$ | $c_{k}$ | $M_{0}$ |
| Total | $N_{1}$ | $N_{2}$ | $\ldots$ | $N_{k}$ | $T$ |

If the tables are stratified, all quantities are indexed by $i$, the stratum number.
We will refer to Fleiss, Levin, and Paik (2003); Kleinbaum, Kupper, and Morgenstern (1982); and Rothman (1986) so often that we will adopt the notation F-23 to mean Fleiss, Levin, and Paik (2003) page 23; KKM-52 to mean Kleinbaum, Kupper, and Morgenstern (1982) page 52; and R-164 to mean Rothman (1986) page 164.

We usually avoid making the continuity corrections to $\chi^{2}$ statistics, following the advice of KKM-292: ". . . the use of a continuity correction has been the subject of considerable debate in the statistical literature .... On the basis of our evaluation of this debate and other evidence, we do not recommend the use of the continuity correction." Breslow and Day (1980, 133), on the other hand, argue for inclusion of the correction, but not strongly. Their summary is that for small datasets, one should use exact statistics. In practice, we believe that the adjustment makes little difference for reasonably sized datasets.

Methods and formulas are presented under the following headings:

```
Unstratified incidence-rate data (ir and iri)
Unstratified cumulative incidence data (cs and csi)
Unstratified case-control data (cc and cci)
Unstratified matched case-control data (mcc and mcci)
Stratified incidence-rate data (ir with the by() option)
Stratified cumulative incidence data (cs with the by() option)
Stratified case-control data (cc with by() option, mhodds, tabodds)
```

## Unstratified incidence-rate data (ir and iri)

The IRD is defined as $I_{d}=a / N_{1}-b / N_{0}$ (R-164). The standard error of the difference is $s_{I_{d}} \approx \sqrt{a / N_{1}^{2}+b / N_{0}^{2}}$ (R-170), from which confidence intervals are calculated.

The IRR is defined as $I_{r}=\left(a / N_{1}\right) /\left(b / N_{0}\right)$ (R-164). Let $p_{l}$ and $p_{u}$ be the exact confidence interval of the binomial probability for observing $a$ successes in $M_{1}$ trials (obtained from cii proportions; see $[\mathrm{R}] \mathbf{c i})$. The exact confidence interval for the incidence ratio is then $\left(p_{l} N_{0}\right) /\left\{\left(1-p_{l}\right) N_{1}\right\}$ to $\left(p_{u} N_{0}\right) /\left\{\left(1-p_{u}\right) N_{1}\right\}$ (R-166).

The AFE is defined as AFE $=\left(I_{r}-1\right) / I_{r}$ for $I_{r} \geq 1$ (КKM-164; R-38); the confidence interval is obtained by similarly transforming the interval values of $I_{r}$. The AFP is AFP $=$ AFE $\cdot a / M_{1}$ (KKM-161); no confidence interval is reported. For $I_{r}<1$, the PFE is defined as PFE $=1-I_{r}$ (KKM-166; R-39); the confidence interval is obtained by similarly transforming the interval values of $I_{r}$. The PFP is $\mathrm{PFP}=\mathrm{PFE} \cdot N_{1} / T$ (KKM-165); no confidence interval is reported.

Exact one-sided $p$-values are calculated as the binomial probabilities (with $n=M_{1}$ and $p=N_{1} / T$ ) $\operatorname{Pr}(k \leq a)$ and $\operatorname{Pr}(k \geq a)$. Exact $p$-values tend to be overly conservative, so the mid- $p$ adjustment ( $\mathrm{R}-155$ ) reduces the exact $p$-values by subtracting half the probability of the observed result from each one-sided $p$-value. That is, one-sided $p$-values with the mid- $p$ adjustment are the binomial probabilities $\operatorname{Pr}(k \leq a)-\operatorname{Pr}(k=a) / 2$ and $\operatorname{Pr}(k \geq a)-\operatorname{Pr}(k=a) / 2$. The two-sided $p$-value is twice the smallest one-sided $p$-value for both the exact and mid- $p$-adjustment calculations. Rather than using twice the smallest one-sided $p$-value for the two-sided $p$-value, there is an another formula for the two-sided $p$-value that is sometimes used. The command bitest uses this alternative; see [R] bitest for details.

## Unstratified cumulative incidence data (cs and csi)

The risk difference is defined as $R_{d}=a / N_{1}-b / N_{0}$ (R-164). Its standard error is

$$
s_{R_{d}} \approx\left\{\frac{a c}{N_{1}^{3}}+\frac{b d}{N_{0}^{3}}\right\}^{1 / 2}
$$

(R-172), from which confidence intervals are calculated.
The risk ratio is defined as $R_{r}=\left(a / N_{1}\right) /\left(b / N_{0}\right)$ (R-165). The standard error of $\ln R_{r}$ is

$$
s_{\ln R_{r}} \approx\left(\frac{c}{a N_{1}}+\frac{d}{b N_{0}}\right)^{1 / 2}
$$

(R-173), from which confidence intervals are calculated.
For $R_{r} \geq 1$, the AFE is calculated as $\mathrm{AFE}=\left(R_{r}-1\right) / R_{r}$ (KKM-164; R-38); the confidence interval is obtained by similarly transforming the interval values for $R_{r}$. The AFP is calculated as $\mathrm{AFP}=\mathrm{AFE} \cdot a / M_{1}$ (KKM-161); no confidence interval is reported, but $\mathrm{F}-128$ provides

$$
\left\{\frac{c+(a+d) \mathrm{AFP}}{b T}\right\}^{1 / 2}
$$

as the approximate standard error of $\ln (1-\mathrm{AFP})$.
For $R_{r}<1$, the PFE is calculated as PFE $=1-R_{r}$ (KKM-166; R-39); the confidence interval is obtained by similarly transforming the interval values for $R_{r}$. The PFP is calculated as PFP $=$ PFE $\cdot N_{1} / T$; no confidence interval is reported.

The odds ratio, available with the or option, is defined as $\psi=(a d) /(b c)$ ( $\mathrm{R}-165$ ). Several confidence intervals are available. The default interval for cs and csi is the Cornfield (1956) approximate interval. If we let $z_{\alpha}$ be the index from a normal distribution for an $\alpha$ significance level, the Cornfield interval $\left(\psi_{l}, \psi_{u}\right)$ is calculated from

$$
\begin{aligned}
\psi_{l} & =a_{l}\left(M_{0}-N_{1}+a_{l}\right) /\left\{\left(N_{1}-a_{l}\right)\left(M_{1}-a_{l}\right)\right\} \\
\psi_{u} & =a_{u}\left(M_{0}-N_{1}+a_{u}\right) /\left\{\left(N_{1}-a_{u}\right)\left(M_{1}-a_{u}\right)\right\}
\end{aligned}
$$

where $a_{u}$ and $a_{l}$ are determined iteratively from

$$
a_{i+1}=a \pm z_{\alpha}\left(\frac{1}{a_{i}}+\frac{1}{N_{1}-a_{i}}+\frac{1}{M_{1}-a_{i}}+\frac{1}{M_{0}-N_{1}+a_{i}}\right)^{-1 / 2}
$$

(Newman 2001, sec. 4.4). $a_{i+1}$ converges to $a_{u}$ using the plus sign and $a_{l}$ using the minus sign. $a_{0}$ is taken as $a$. With small numbers, the iterative technique may fail. It is then restarted by decrementing ( $a_{l}$ ) or incrementing $\left(a_{u}\right) a_{0}$. If that fails, $a_{0}$ is again decremented or incremented and iterations restarted, and so on, until a terminal condition is met ( $a_{0}<0$ or $a_{0}>M_{1}$ ), at which point the value is not calculated.

The Woolf odds-ratio confidence intervals are available with cs and csi. The Woolf method (Woolf 1955; R-173; Schlesselman 1982, 176), available with the woolf option, estimates the standard error of $\ln \psi$ by

$$
s_{\ln \psi}=\left(\frac{1}{a}+\frac{1}{b}+\frac{1}{c}+\frac{1}{d}\right)^{1 / 2}
$$

from which confidence intervals are calculated. The Woolf interval cannot be calculated when there exists a zero cell. Sometimes the Woolf interval is called the "logit interval" (Breslow and Day 1980, 134).

The $\chi^{2}$ statistic, reported by default, can be calculated as

$$
\chi^{2}=\frac{(a d-b c)^{2} T}{M_{1} M_{0} N_{1} N_{0}}
$$

(Schlesselman 1982, 179).
Fisher's exact test, available with the exact option, is calculated as described in $[R]$ tabulate twoway.

## Unstratified case-control data (cc and cci)

cc and cci report by default the same odds ratio, $\psi$, that is available with the or option in cs and csi. But cc and cci calculate the confidence interval differently: they default to the exact odds-ratio interval, not the Cornfield interval, but you can request the Cornfield interval with the cornfield option. The $1-\alpha$ exact interval $(\underline{R}, \bar{R})$ is calculated from

$$
\alpha / 2=\frac{\sum_{k=a}^{\min \left(N_{1}, M_{1}\right)}\binom{N_{1}}{k}\binom{N_{0}}{M_{1}-k} \underline{R}^{k}}{\sum_{k=\max \left(0, M_{1}-N_{0}\right)}^{\min \left(N_{1}, M_{1}\right)}\binom{N_{1}}{k}\binom{N_{0}}{M_{1}-k} \underline{R}^{k}}
$$

and

$$
1-\alpha / 2=\frac{\sum_{k=a+1}^{\min \left(N_{1}, M_{1}\right)}\binom{N_{1}}{k}\binom{N_{0}}{M_{1}-k} \bar{R}^{k}}{\sum_{k=\max \left(0, M_{1}-N_{0}\right)}^{\min \left(N_{1}, M_{1}\right)}\binom{N_{1}}{k}\binom{N_{0}}{M_{1}-k} \bar{R}^{k}}
$$

( $\mathrm{R}-169$ ). The equations invert two one-sided Fisher exact tests.
cc and cci also report the same tests of significance as cs and csi: the $\chi^{2}$ statistic is the default, and Fisher's exact test is obtained with the exact option. The odds ratio, $\psi$, is used as an estimate of the risk ratio in calculating attributable or prevented fractions. For $\psi \geq 1$, the AFE is calculated as $\mathrm{AFE}=(\psi-1) / \psi($ KKM-164 $)$; the confidence interval is obtained by similarly transforming the interval values for $\psi$. The AFP is calculated as AFP $=$ AFE $\cdot a / M_{1}$ (KKM-161). No confidence interval is reported; however, F-152 provides

$$
\left(\frac{a}{M_{1} b}+\frac{c}{M_{0} d}\right)^{1 / 2}
$$

as the standard error of $\ln (1-\mathrm{AFP})$.
For $\psi<1$, the PFE is calculated as PFE $=1-\psi$ (KKM-166); the confidence interval is obtained by similarly transforming the interval values for $\psi$. The PFP is calculated as $\operatorname{PFP}=\left\{\left(a / M_{1}\right) \mathrm{PFE}\right\} /\left\{\left(a / M_{1}\right) \mathrm{PFE}+\psi\right\}$ (KKM-165); no confidence interval is reported.

## Unstratified matched case-control data (mcc and mcci)

Referring to the table at the beginning of Matched case-control data under Remarks and examples above, the columns of the table indicate controls; the rows are cases. Each entry in the table reflects a pair of a matched case and control.

McNemar's (1947) $\chi^{2}$ is defined as

$$
\chi^{2}=\frac{(b-c)^{2}}{b+c}
$$

(ККМ-389).
The proportion of controls with the factor is $p_{1}=N_{1} / T$, and the proportion of cases with the factor is $p_{2}=M_{1} / T$.

The difference in the proportions is $P_{d}=p_{2}-p_{1}$. An estimate of its standard error when the two underlying proportions are not hypothesized to be equal is

$$
s_{P_{d}} \approx \frac{\{(a+d)(b+c)+4 b c\}^{1 / 2}}{T^{3 / 2}}
$$

(F-378), from which confidence intervals are calculated. The confidence interval uses a continuity correction (F-378, eq. 13.15).

The ratio of the proportions is $P_{r}=p_{2} / p_{1}(\mathrm{R}-276, \mathrm{R}-278)$. The standard error of $\ln P_{r}$ is

$$
s_{\ln P_{r}} \approx\left(\frac{b+c}{M_{1} N_{1}}\right)^{1 / 2}
$$

(R-276), from which confidence intervals are calculated.
The relative difference in the proportions is $P_{e}=(b-c) /(b+d)$ (F-379). Its standard error is

$$
s_{P_{e}} \approx(b+d)^{-2}\{(b+c+d)(b c+b d+c d)-b c d\}^{1 / 2}
$$

(F-379), from which confidence intervals are calculated.
The odds ratio is $\psi=b / c$ ( $\mathrm{F}-376$ ), and the exact Fisher confidence interval is obtained by transforming into odds ratios the exact binomial confidence interval for the binomial parameter from observing $b$ successes in $b+c$ trials (R-264). Binomial confidence limits are obtained from cii proportions (see [R] ci) and are transformed by $p /(1-p)$.

The exact McNemar significance probability is a two-tailed exact test of $H_{0}: \psi=1$. The $p$-value, calculated from the binomial distribution, is

$$
\min \left\{1,2 \sum_{k=0}^{\min (b, c)}\binom{b+c}{k}\left(\frac{1}{2}\right)^{b+c}\right\}
$$

(Agresti 2013, 416).

Quinn McNemar (1900-1986) was born in West Virginia and attended college there and in Pennsylvania. After a brief spell of high school teaching, he began graduate study of psychology at Stanford and then joined the faculty. McNemar's text Psychological Statistics, first published in 1949, was widely influential, and he made many substantive and methodological contributions to the application of statistics in psychology.

## Stratified incidence-rate data (ir with the by() option)

Statistics presented for each stratum are calculated independently according to the formulas in Unstratified incidence-rate data (ir and iri) above. Within strata, the Mantel-Haenszel style weight is $W_{i}=b_{i} N_{1 i} / T_{i}$, and the Mantel-Haenszel combined incidence-rate ratio (Rothman and Boice 1982) is

$$
I_{\mathrm{mh}}=\frac{\sum_{i} a_{i} N_{0 i} / T_{i}}{\sum_{i} W_{i}}
$$

( $\mathrm{R}-196$ ). The standard error for the $\log$ of the incidence-rate ratio was derived by Greenland and Robins $(1985,63)$ and appears in R-213:

$$
s_{\ln I_{\mathrm{mh}}} \approx\left\{\frac{\sum_{i} M_{1 i} N_{1 i} N_{0 i} / T_{i}^{2}}{\left(\sum_{i} a_{i} N_{0 i} / T_{i}\right)\left(\sum_{i} b_{i} N_{1 i} / T_{i}\right)}\right\}^{1 / 2}
$$

The confidence interval is calculated first on the $\log$ scale and then is transformed.
For standardized rates, let $w_{i}$ be the user-specified weight within stratum $i$. The standardized rate difference (the ird option) and rate ratio are defined as

$$
\begin{aligned}
\mathrm{SRD} & =\frac{\sum_{i} w_{i}\left(R_{1 i}-R_{0 i}\right)}{\sum_{i} w_{i}} \\
\mathrm{SRR} & =\frac{\sum_{i} w_{i} R_{1 i}}{\sum_{i} w_{i} R_{0 i}}
\end{aligned}
$$

( $\mathrm{R}-229$ ). The standard error of SRD is

$$
s_{\mathrm{SRD}} \approx\left\{\frac{1}{\left(\sum_{i} w_{i}\right)^{2}} \sum_{i} w_{i}^{2}\left(\frac{a_{i}}{N_{1 i}^{2}}+\frac{b_{i}}{N_{0 i}^{2}}\right)\right\}^{1 / 2}
$$

(R-231), from which confidence intervals are calculated. The standard error of $\ln (S R R)$ is

$$
s_{\ln (\mathrm{SRR})} \approx\left\{\frac{\sum_{i} w_{i}^{2} a_{i} / N_{1 i}^{2}}{\left(\sum_{i} w_{i} R_{1 i}\right)^{2}}+\frac{\sum_{i} w_{i}^{2} b_{i} / N_{0 i}^{2}}{\left(\sum_{i} w_{i} R_{0 i}\right)^{2}}\right\}^{1 / 2}
$$

( $\mathrm{R}-231$ ), from which confidence intervals are calculated.
Internally and externally standardized measures are calculated using $w_{i}=N_{1 i}$ and $w_{i}=N_{0 i}$, respectively, and are obtained with the istandard and estandard options, respectively.

Directly pooled estimates are available with the pool option. The directly pooled estimate is a weighted average of stratum-specific estimates; each weight, $w_{i}$, is inversely proportional to the variance of the estimate for stratum $i$. The variances for rate differences come from the formulas in Unstratified incidence-rate data (ir and iri), while the variances of log rate-ratios are estimated by $\left(1 / a_{i}+1 / b_{i}\right)$ (R-184). Ratios are averaged in the log scale before being exponentiated. The standard error of the directly pooled estimate is calculated as $1 / \sqrt{\sum w_{i}}$, from which confidence intervals are calculated (R-183-185); the calculation for ratios again uses the log scale.

For rate differences, the $\chi^{2}$ test of homogeneity is calculated as $\sum\left(R_{d i}-\widehat{R}_{d}\right)^{2} / \operatorname{var}\left(R_{d i}\right)$, where $R_{d i}$ are the stratum-specific rate differences and $\widehat{R}_{d}$ is the directly pooled estimate. The number of degrees of freedom is one less than the number of strata ( $\mathrm{R}-222$ ).

For rate ratios, the same calculation is made, except that it is made on a logarithmic scale using $\ln \left(R_{r i}\right)$ (R-222), and $\ln \left(\widehat{R}_{d}\right)$ may be the $\log$ of either the directly pooled estimate or the Mantel-Haenszel estimate.

## Stratified cumulative incidence data (cs with the by() option)

Statistics presented for each stratum are calculated independently according to the formulas in Unstratified cumulative incidence data (cs and csi) above. The Mantel-Haenszel $\chi^{2}$ test (Mantel and Haenszel 1959) is

$$
\chi_{\mathrm{mh}}^{2}=\frac{\left\{\sum_{i}\left(a_{i}-N_{1 i} M_{1 i} / T_{i}\right)\right\}^{2}}{\sum_{i}\left(N_{1 i} N_{0 i} M_{1 i} M_{0 i}\right) /\left\{T_{i}^{2}\left(T_{i}-1\right)\right\}}
$$

(R-206).
For the odds ratio (available with the or option), the Mantel-Haenszel weight is $W_{i}=b_{i} c_{i} / T_{i}$, and the combined odds ratio (Mantel and Haenszel 1959) is

$$
\psi_{\mathrm{mh}}=\frac{\sum_{i} a_{i} d_{i} / T_{i}}{\sum_{i} W_{i}}
$$

( $\mathrm{R}-195$ ). The standard error (Robins, Breslow, and Greenland 1986) is

$$
s_{\ln \psi_{\mathrm{mh}}} \approx\left\{\frac{\sum_{i} P_{i} R_{i}}{2\left(\sum_{i} R_{i}\right)^{2}}+\frac{\sum_{i} P_{i} S_{i}+Q_{i} R_{i}}{2 \sum_{i} R_{i} \sum_{i} S_{i}}+\frac{\sum_{i} Q_{i} S_{i}}{2\left(\sum_{i} S_{i}\right)^{2}}\right\}^{1 / 2}
$$

where

$$
\begin{aligned}
P_{i} & =\left(a_{i}+d_{i}\right) / T_{i} \\
Q_{i} & =\left(b_{i}+c_{i}\right) / T_{i} \\
R_{i} & =a_{i} d_{i} / T_{i} \\
S_{i} & =b_{i} c_{i} / T_{i}
\end{aligned}
$$

(R-220).
For the risk ratio (the default), the Mantel-Haenszel-style weight is $W_{i}=b_{i} N_{1 i} / T_{i}$, and the combined risk ratio (Rothman and Boice 1982) is

$$
R_{\mathrm{mh}}=\frac{\sum_{i} a_{i} N_{0 i} / T_{i}}{\sum_{i} W_{i}}
$$

( R -196). The standard error (Greenland and Robins 1985) is

$$
s_{\ln R_{\mathrm{mh}}} \approx\left\{\frac{\sum_{i}\left(M_{1 i} N_{1 i} N_{0 i}-a_{i} b_{i} T_{i}\right) / T_{i}^{2}}{\left(\sum_{i} a_{i} N_{0 i} / T_{i}\right)\left(\sum_{i} b_{i} N_{1 i} / T_{i}\right)}\right\}^{1 / 2}
$$

( $\mathrm{R}-216$ ), from which confidence intervals are calculated.
For standardized rates, let $w_{i}$ be the user-specified weight within stratum $i$. The standardized rate difference (SRD, the rd option) and rate ratios (SRR, the default) are defined as in Stratified incidence-rate data (ir with the by() option), where the individual risks are defined $R_{1 i}=a_{i} / N_{1 i}$ and $R_{0 i}=b_{i} / N_{0 i}$. The standard error of SRD is

$$
s_{\mathrm{SRD}} \approx\left[\frac{1}{\left(\sum_{i} w_{i}\right)^{2}} \sum_{i} w_{i}^{2}\left\{\frac{a_{i}\left(N_{1 i}-a_{i}\right)}{N_{1 i}^{3}}+\frac{b_{i}\left(N_{0 i}-b_{i}\right)}{N_{0 i}^{3}}\right\}\right]^{1 / 2}
$$

( $\mathrm{R}-231$ ), from which confidence intervals are calculated. The standard error of $\ln (\mathrm{SRR})$ is

$$
s_{\ln (\mathrm{SRR})} \approx\left\{\frac{\sum_{i} w_{i}^{2} a_{i}\left(N_{1 i}-a_{i}\right) / N_{1 i}^{3}}{\left(\sum_{i} w_{i} R_{1 i}\right)^{2}}+\frac{\sum_{i} w_{i}^{2} b_{i}\left(N_{0 i}-b_{i}\right) / N_{0 i}^{3}}{\left(\sum_{i} w_{i} R_{0 i}\right)^{2}}\right\}^{1 / 2}
$$

( $\mathrm{R}-231$ ), from which confidence intervals are calculated.
Internally and externally standardized measures are calculated using $w_{i}=N_{1 i}$ and $w_{i}=N_{0 i}$, respectively, and are obtained with the istandard and estandard options, respectively.

Directly pooled estimates of the odds ratio are available when you specify both the pool and or options. The directly pooled estimate is a weighted average of stratum-specific log odds-ratios; each weight, $w_{i}$, is inversely proportional to the variance of the log odds-ratio for stratum $i$. The variances of the log odds-ratios are estimated by Woolf's method, described under Unstratified cumulative incidence data (cs and csi). The standard error of the directly pooled log odds-ratio is calculated as $1 / \sqrt{\sum w_{i}}$, from which confidence intervals are calculated and then exponentiated (Kahn and Sempos 1989, 113-115).

Direct pooling is also available for risk ratios and risk differences; the variance formulas may be found in Unstratified cumulative incidence data (cs and csi). The directly pooled risk ratio is provided when the pool option is specified. The directly pooled risk difference is provided only when you specify the pool and rd options, and one of the estandard, istandard, and standard() options.

For risk differences, the $\chi^{2}$ test of homogeneity is calculated as $\sum\left(R_{d i}-\widehat{R}_{d}\right)^{2} / \operatorname{var}\left(R_{d i}\right)$, where $R_{d i}$ are the stratum-specific risk differences and $\widehat{R}_{d}$ is the directly pooled estimate. The number of degrees of freedom is one less than the number of strata ( $\mathrm{R}-222$ ).

For risk and odds ratios, the same calculation is made, except that it is made in the log scale using $\ln \left(R_{r i}\right)$ or $\ln \left(\psi_{i}\right)$ (R-222), and $\ln \left(\widehat{R}_{d}\right)$ may be the $\log$ of either the directly pooled estimate or the Mantel-Haenszel estimate.

## Stratified case-control data (cc with by() option, mhodds, tabodds)

Statistics presented for each stratum are calculated independently according to the formulas in Unstratified cumulative incidence data (cs and csi) above. The combined odds ratio, $\psi_{\mathrm{mh}}$, and the test that $\psi_{\mathrm{mh}}=1\left(\chi_{\mathrm{mh}}^{2}\right)$ are calculated as described in Stratified cumulative incidence data (cs with the by() option) above.

For standardized weights, let $w_{i}$ be the user-specified weight within stratum $i$. The standardized odds ratio (the standard() option) is calculated as

$$
\mathrm{SOR}=\frac{\sum_{i} w_{i} a_{i} / c_{i}}{\sum_{i} w_{i} b_{i} / d_{i}}
$$

(Greenland 1986, 473). The standard error of $\ln (S O R)$ is

$$
s_{\ln (\mathrm{SOR})}=\left\{\frac{\sum_{i}\left(w_{i} a_{i} / c_{i}\right)^{2}\left(\frac{1}{a_{i}}+\frac{1}{b_{i}}+\frac{1}{c_{i}}+\frac{1}{d_{i}}\right)}{\left(\sum_{i} w_{i} a_{i} / c_{i}\right)^{2}}\right\}^{1 / 2}
$$

from which confidence intervals are calculated. The internally and externally standardized odds ratios are calculated using $w_{i}=c_{i}$ and $w_{i}=d_{i}$, respectively.

The directly pooled estimate of the odds ratio (the pool option) is calculated as described in Stratified cumulative incidence data (cs with the by() option) above.

The directly pooled and Mantel-Haenszel $\chi^{2}$ tests of homogeneity are calculated as $\sum\left\{\ln \left(R_{r i}\right)-\right.$ $\left.\ln \left(\widehat{R}_{r}\right)\right\}^{2} / \operatorname{var}\left\{\ln \left(R_{r i}\right)\right\}$, where $R_{r i}$ are the stratum-specific odds ratios and $\widehat{R}_{r}$ is the pooled estimate (Mantel-Haenszel or directly pooled). The number of degrees of freedom is one less than the number of strata (R-222).

The Breslow-Day $\chi^{2}$ test of homogeneity is available with the bd option. Let $\widehat{\psi}$ be the MantelHaenszel estimate of the common odds ratio, and let $A_{i}(\widehat{\psi})$ be the fitted count for cell $a$; $A_{i}(\widehat{\psi})$ is found by solving the quadratic equation

$$
A\left(M_{0}-N_{1}+A\right)=(\widehat{\psi})\left(M_{1}-A\right)\left(N_{1}-A\right)
$$

and choosing the root that makes all cells in stratum $i$ positive. Let $\operatorname{Var}\left(a_{i} ; \widehat{\psi}\right)$ be the estimated variance of $a_{i}$ conditioned on the margins and on an odds ratio of $\widehat{\psi}$ :

$$
\operatorname{Var}\left(a_{i} ; \widehat{\psi}\right)=\left\{\frac{1}{A_{i}(\widehat{\psi})}+\frac{1}{M_{1 i}-A_{i}(\widehat{\psi})}+\frac{1}{N_{1 i}-A_{i}(\widehat{\psi})}+\frac{1}{M_{0 i}-N_{1 i}+A_{i}(\widehat{\psi})}\right\}^{-1}
$$

The Breslow-Day $\chi^{2}$ statistic is then

$$
\sum_{i} \frac{\left\{a_{i}-A_{i}(\widehat{\psi})\right\}^{2}}{\operatorname{Var}\left(a_{i} ; \widehat{\psi}\right)}
$$

The Tarone $\chi^{2}$ test of homogeneity (the tarone option) is calculated as

$$
\sum_{i} \frac{\left\{a_{i}-A_{i}(\widehat{\psi})\right\}^{2}}{\operatorname{Var}\left(a_{i} ; \widehat{\psi}\right)}-\frac{\left\{\sum_{i} a_{i}-\sum_{i} A_{i}(\widehat{\psi})\right\}^{2}}{\sum_{i} \operatorname{Var}\left(a_{i} ; \widehat{\psi}\right)}
$$

Tarone (1985) provides this correction to the Breslow-Day statistic to ensure that its distribution is asymptotically $\chi^{2}$. Without the correction, the Breslow-Day statistic does not necessarily follow a $\chi^{2}$ distribution because it is based on the Mantel-Haenszel estimate, $\widehat{\psi}$, which is an inefficient estimator of the common odds ratio.

When the exposure variable has multiple levels, mhodds calculates an approximate estimate of the $\log$ odds-ratio for a one-unit increase in exposure as the ratio of the score statistic, $U$, to its variance, $V$ (Clayton and Hills 1993, 103), which are defined below. This is a one-step NewtonRaphson approximation to the maximum likelihood estimate. Within-stratum estimates are combined with Mantel-Haenszel weights.

By default, both tabodds and mhodds produce test statistics and confidence intervals based on score statistics (Clayton and Hills 1993). tabodds reports confidence intervals for the odds of the $i$ th exposure level, unless the adjust () or or option is specified. The confidence interval for odds ${ }_{i}$, $i=1, \ldots, k$, is given by

$$
\operatorname{odds}_{i} \cdot \exp \left( \pm z \sqrt{1 / a_{i}+1 / c_{i}}\right)
$$

The score $\chi^{2}$ test of homogeneity of odds is calculated as

$$
\chi_{k-1}^{2}=\frac{T(T-1)}{M_{1} M_{0}} \sum_{i=1}^{k} \frac{\left(a_{i}-E_{i}\right)^{2}}{N_{i}}
$$

where $E_{i}=\left(M_{1} N_{i}\right) / T$.

Let $l_{i}$ denote the value of the exposure at the $i$ th level. The score $\chi^{2}$ test for trend of odds is calculated as

$$
\chi_{1}^{2}=\frac{U^{2}}{V}
$$

where

$$
U=\frac{M_{1} M_{0}}{T}\left(\sum_{i=1}^{k} \frac{a_{i} l_{i}}{M_{1}}-\sum_{i=1}^{k} \frac{c_{i} l_{i}}{M_{0}}\right)
$$

and

$$
V=\frac{M_{1} M_{0}}{T}\left\{\frac{\sum_{i=1}^{k} N_{i} l_{i}^{2}-\left(\sum_{i=1}^{k} N_{i} l_{i}\right)^{2} / T}{T-1}\right\}
$$

## Acknowledgments

We thank Hal Morgenstern, professor emeritus of the Department of Epidemiology at the University of Michigan, Ardythe Morrow of Cincinnati Children's Hospital, and the late Stewart West of Baylor College of Medicine for their assistance in designing these commands.

We thank Jonathan Freeman (1939-2000) of the Department of Epidemiology at Harvard School of Public Health for encouraging us to extend these commands to include tests for homogeneity, for helpful comments on the default behavior of the commands, and for his comments on an early draft of this section.

We thank David Clayton (retired) of the Cambridge Institute for Medical Research and Michael Hills (1934-2021) of the London School of Hygiene and Tropical Medicine, who wrote the original versions of mhodds and tabodds.

Finally, we thank William Dupont and Dale Plummer, both at the Department of Biostatistics, Vanderbilt University, for their contribution to the implementation of exact confidence intervals for the odds ratios for cc and cci.

John Snow (1813-1858) was born in York, England. From age 14, he worked as an apprentice and assistant to surgeons in northeast England and Yorkshire. In 1836, Snow moved to London; he was admitted to the Royal College of Surgeons in 1838 and the Royal College of Physicians in 1850. He made outstanding contributions to the adoption of anesthesia and is considered one of the originators of modern epidemiology. Snow died following a stroke in 1858.

Snow calculated dosages for ether and chloroform. He personally administered chloroform to Queen Victoria for the births of her last two children, which helped obstetric anesthesia gain wider acceptance.

Snow was skeptical of the miasma theory that cholera was caused by foul air. His essay On the Mode of Communication of Cholera was first published in 1849 and then greatly enlarged in 1855 with the results of his very detailed investigation of the role of water supply in the epidemic of 1854 in the Soho district of London. Snow identified the source of the outbreak as the public water pump on Broad Street (now Broadwick Street), leading the local council to remove the pump handle. It was later discovered that the well had been dug very close to an old cesspit. He also mapped the clustering of cholera cases around the pump and related mortality to water sources, clearly showing higher deathrates in areas supplied by the Southwark and Vauxhall Waterworks Company, which was taking water from sewage-polluted sections of the River Thames. Snow is widely regarded as a pioneer in public health, epidemiology, and medical geography.

Janet Elizabeth Lane-Claypon (1877-1967) was a pioneer in the use of cohort and case-control studies. She was born in Lincolnshire county, England, and began her studies at the London School of Medicine for Women in 1898. From 1907 to 1912, she was at the Lister Institute of Preventive Medicine, where she was a colleague of Major Greenwood. By the end of her studies, she had obtained a doctorate in both physiology and medicine.

In 1912, Lane-Claypon published one of the first retrospective cohort studies, examining the weight gain of babies fed cow's milk versus babies fed breast milk. Using statistical techniques, she determined that babies fed breast milk gained weight faster; she later employed that knowledge to become a public health advocate for breast feeding.

She also conducted one of the first case-control studies, examining risk factors associated with breast cancer. Her study included 500 women without breast cancer and 500 women with breast cancer. To obtain what was at the time a remarkably large sample, she coordinated data collection from nine different hospitals. Carefully controlling for variables including occupation and infant mortality, she determined that factors like age at first pregnancy, age at menopause, and number of children all influence the incidence of breast cancer; these factors are still considered to be among the prime determinants.

In conjunction with the Ministry of Health, in 1926 Lane-Claypon published one of the first studies to contain long-term follow-up results. In that study, she followed patients who had undergone surgery for breast cancer for up to 10 years after the operation. As is still the case today, her study showed that the sooner the cancer was treated, the better the woman's chance for long-term survival. Notably, her study was also among the first to consider survivorship bias.

## Title

Error messages - Error messages and return codes

## Description Also see

## Description

Whenever Stata detects that something is wrong-that what you typed is uninterpretable, that you are trying to do something you should not be trying to do, or that you requested the impossible - Stata responds by typing a message describing the problem, together with a return code. For instance,

```
. lsit
command lsit is unrecognized
r(199);
. list myvar
variable myvar not found
r(111);
. test a=b
last estimates not found
r(301);
```

In each case, the message is probably sufficient to guide you to a solution. When we typed lsit, Stata responded with "unrecognized command". We meant to type list. When we typed list myvar, Stata responded with "variable myvar not found". There is no variable named myvar in our data. When we typed test $\mathrm{a}=\mathrm{b}$, Stata responded with "last estimates not found". test tests hypotheses about previously fit models, and we have not yet fit a model.

The numbers in parentheses in the $r(199), r(111)$, and $r(301)$ messages are called the return codes. To find out more about these messages, type search rc \#, where \# is the number returned in the parentheses.

## > Example 1

. search rc 301
[P] error messages . . . . . . . . . . . . . . . . . . . . Return code 301
last estimates not found;
You typed an estimation command, such as regress, without arguments or attempted to perform a test or typed predict, but there were no previous estimation results.

Programmers should see [P] error for details on programming error messages.

## Title

esize - Effect size based on mean comparison

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

esize calculates effect sizes for comparing the difference between the means of a continuous variable for two groups. In the first form, esize calculates effect sizes for the difference between the mean of varname for two groups defined by groupvar. In the second form, esize calculates effect sizes for the difference between varname $_{1}$ and varname ${ }_{2}$, assuming unpaired data.
esizei is the immediate form of esize; see [U] 19 Immediate commands. In the first form, esizei calculates the effect size for comparing the difference between the means of two groups. In the second form, esizei calculates the effect size for an $F$ test after an ANOVA.

## Quick start

Cohen's $d$ and Hedges's $g$ comparing the difference in means of v for two independent groups in catvar

```
esize twosample v, by(catvar)
```

Same as above, but with group data stored in v1 and v2
esize unpaired $\mathrm{v} 1==\mathrm{v} 2$
Same as above, but use $90 \%$ confidence level
esize unpaired v1==v2, level(90)
Cohen's $d$ and Hedges's $g$ for means of v for groups in catvar1 calculated over each level of catvar2
by catvar2: esize twosample v, by(catvar1)

## Menu

esize
Statistics $>$ Summaries, tables, and tests $>$ Classical tests of hypotheses $>$ Effect size based on mean comparison

## esizei

Statistics $>$ Summaries, tables, and tests $>$ Classical tests of hypotheses $>$ Effect-size calculator

## Syntax

Effect sizes for two independent samples using groups

```
esize twosample varname [if] [in], by(groupvar) [options]
```

Effect sizes for two independent samples using variables

```
esize unpaired varname}\mp@subsup{1}{1}{\prime== varname 2 [if] [in], [options]
```

Immediate form of effect sizes for two independent samples

$$
\text { esizei } \#_{\text {obs1 }} \#_{\text {mean } 1} \#_{\text {sd1 }} \#_{\text {obs2 }} \#_{\text {mean2 }} \#_{\text {sd2 }}[\text {, options }]
$$

Immediate form of effect sizes for $F$ tests after an ANOVA

```
esizei # df1 # #ff2 #F [, level(#)]
```

options
Description
Main
cohensd report Cohen's $d$ (1988)
hedgesg report Hedges's $g$ (1981)
glassdelta report Glass's $\Delta$ (Smith and Glass 1977) using each group's standard deviation
pbcorr
report the point-biserial correlation coefficient (Pearson 1909)
all report all estimates of effect size
unequal use unequal variances
welch use Welch's (1947) approximation
level(\#) set confidence level; default is level(95)
by is allowed with esize, and collect is allowed with esize and esizei; see [U] 11.1.10 Prefix commands.

## Options

$\qquad$ Main
by (groupvar) specifies the groupvar that defines the two groups that esize will use to estimate the effect sizes. Do not confuse the by () option with the by prefix; you can specify both.
cohensd specifies that Cohen's $d$ (1988) be reported.
hedgesg specifies that Hedges's $g$ (1981) be reported.
glassdelta specifies that Glass's $\Delta$ (Smith and Glass 1977) be reported.
pbcorr specifies that the point-biserial correlation coefficient (Pearson 1909) be reported.
all specifies that all estimates of effect size be reported. The default is Cohen's $d$ and Hedges's $g$. unequal specifies that the data not be assumed to have equal variances.
welch specifies that the approximate degrees of freedom for the test be obtained from Welch's formula (1947) rather than from Satterthwaite's approximation formula (1946), which is the default when unequal is specified. Specifying welch implies unequal.
level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

## Remarks and examples

Remarks are presented under the following headings:

Introduction<br>Estimating effect sizes<br>Immediate form<br>Video example

## Introduction

Whereas $p$-values are used to assess the statistical significance of a result, measures of effect size are used to assess the practical significance of a result. Effect sizes can be broadly categorized as "measures of group differences" (the $d$ family) and "measures of association" (the $r$ family); see Ellis (2010, table 1.1). The $d$ family includes estimators such as Cohen's $d$, Hedges's $g$, and Glass's $\Delta$. The $r$ family includes estimators such as the point-biserial correlation coefficient, $\eta^{2}, \varepsilon^{2}$, and $\omega^{2}$ (also see estat esize in [R] regress postestimation). For an introduction to the concepts and calculation of effect sizes, see Kline (2013) and Thompson (2006). For a more detailed discussion, see Kirk (1996), Ellis (2010), Cumming (2012), Grissom and Kim (2012), and Kelley and Preacher (2012).

Note that there is much variation in the definitions of measures of effect size (Kline 2013). As Ellis (2010, 27) cautions, "However, beware the inconsistent terminology. What is labeled here as $g$ was labeled by Hedges and Olkin as $d$ and vice versa. For these authors writing in the early 1980s, $g$ was the mainstream effect-size index developed by Cohen and refined by Glass (hence $g$ for Glass). However, since then $g$ has become synonymous with Hedges's equation (not Glass's) and the reason it is called Hedges's $g$ and not Hedges's $h$ is because it was originally named after Glass-even though it was developed by Larry Hedges. Confused?"

To avoid confusion, esize and esizei closely follow the notation of Hedges (1981), Smithson (2001), Kline (2013), and Ellis (2010).

## Estimating effect sizes

> Example 1: Effect size for two independent samples using by()
Suppose we are interested in question 1 from the fictitious depression.dta: "My statistical software makes me feel sad". We might have conducted a $t$ test to test the null hypothesis that there is no difference in response by sex. We could then compute various measures of effect size to describe the magnitude of the effect of sex.

| (Fictitious depression inventory dat esize twosample qu1, by (sex) all Effect size based on mean comparison |  |  |  |
| :---: | :---: | :---: | :---: |
| Obs per group: |  |  |  |
|  |  | Female $=$ | 712 |
|  |  | Male | 288 |
| Effect size | Estimate | [95\% conf | interval] |
| Cohen's d | -. 0512417 | -. 1881184 | . 0856607 |
| Hedges's $g$ | -. 0512032 | -. 187977 | . 0855963 |
| Glass's Delta 1 | -. 0517793 | -. 1886587 | . 0851364 |
| Glass's Delta 2 | -. 0499786 | -. 1868673 | . 086997 |
| Point-biserial r | -. 0232208 | -. 0849629 | . 0387995 |

Cohen's $d$, Hedges's $g$, and both estimates of Glass's $\Delta$ indicate that the score for females is 0.05 standard deviations lower than the score for males. The point-biserial correlation coefficient indicates that there is a small, negative correlation between the scores for females and males.

## - Technical note

Glass's $\Delta$ has traditionally been estimated for experimental studies using the control group standard deviation rather than the pooled standard deviation. Kline (2013) notes that the choice of group becomes arbitrary for data arising from observational studies and recommends the reporting of Glass's $\Delta$ using each group standard deviation.

Example 2: Effect size for two independent samples by a third variable
If we are interested in the same effect sizes from example 1 stratified by race, we could use the by prefix with the sort option to accomplish this task.

```
. by race, sort: esize twosample qu1, by(sex)
```

```
-> race = Hispanic
Effect size based on mean comparison
```

        Obs per group:
        Female \(=\quad 88\)
            Male \(=\quad 45\)
    | Effect size | Estimate | $[95 \%$ conf. interval] |  |
| ---: | ---: | :---: | ---: |
| Cohen's d | -.1042883 | -.463503 | .2553235 |
| Hedges's g | -.1036899 | -.4608434 | .2538584 |

```
-> race = Black
Effect size based on mean comparison
```

    Obs per group:
        Female \(=\quad 259\)
        Male \(=\quad 95\)
    | Effect size | Estimate | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: |
| Cohen's d | -.1720681 | -.4073814 | .063489 |
| Hedges's g | -.1717011 | -.4065127 | .0633536 |

-> race = White
Effect size based on mean comparison
Obs per group:
Female $=365$
Male = 148

| Effect size | Estimate | $[95 \%$ conf. interval] |  |
| ---: | :---: | :---: | ---: |
| Cohen's d | .0479511 | -.1430932 | .2389486 |
| Hedges's g | .0478807 | -.1428831 | .2385977 |

## > Example 3: Bootstrap confidence intervals for effect sizes

Simulation studies have shown that bootstrap confidence intervals may be preferable to confidence intervals based on the noncentral $t$ distribution when the variable of interest does not have a normal distribution (Kelley 2005; Algina, Keselman, and Penfield 2006). Bootstrap confidence intervals can be easily estimated for effect sizes using the bootstrap prefix.

| (Fictitious depression inventory data based on the Beck Depression Inventory) <br> . set seed 12345 <br> . bootstrap $r(d) r(g)$, reps(1000) nodots nowarn: esize twosample qu1, by (sex) <br> Bootstrap results <br> Number of obs $=1,000$ <br> Replications $=1,000$ <br> Command: esize twosample qu1, by(sex) _bs_1: r(d) _bs_2: r(g) |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Observed coefficient | Bootstrap std. err. | z | $P>\|z\|$ | $\begin{array}{r} \text { Norm } \\ {[95 \% \text { con }} \end{array}$ | based <br> interval] |
| _bs_1 | -. 0512417 | . 0742692 | -0.69 | 0.490 | -. 1968066 | . 0943233 |
| _bs_2 | -. 0512032 | . 0742134 | -0.69 | 0.490 | -. 1966587 | . 0942523 |

## > Example 4: Effect sizes for two independent samples using variables

Sometimes, the data of interest are stored in two separate variables. We can calculate effect sizes for the two groups by using the unpaired version of esize.

| - use https://www.stata-press.com/data/r18/fuel |  |  |  |
| :--- | :---: | :---: | :---: |
| . esize unpaired mpg1==mpg2 |  |  |  |
| Effect size based on mean comparison |  |  |  |
| Number of obs $=$ |  |  |  |
| 24    <br> Effect size Estimate [95\% conf. interval]  <br> Cohen's d -.5829654 -1.394934 .2416105 <br> Hedges's g -.5628243 -1.34674 .2332631 |  |  |  |

## Immediate form

## Example 5: Immediate form for effect sizes for two means

Often we do not have access to raw data, but we are given summary statistics in a report or manuscript. To calculate the effect sizes from summary statistics, we can use the immediate command esizei. For example, Kline (2013) in table 4.2 shows summary statistics for a hypothetical sample where mean $_{1}=13, \operatorname{sd}_{1}=2.74$, mean $_{2}=11$, and $\mathrm{sd}_{2}=2.24$; there are 30 people in each group. We can estimate the effect sizes from these summary data using esizei:

|  |  | er group: <br> Group 1 <br> Group 2 | $\begin{aligned} & 30 \\ & 30 \end{aligned}$ |
| :---: | :---: | :---: | :---: |
| Effect size | Estimate | [95\% con | interval] |
| Cohen's d | . 7991948 | . 2695509 | 1.322465 |
| Hedges's g | . 7888081 | . 2660477 | 1.305277 |

## Example 6: Immediate form for effect sizes for F tests after an ANOVA

esizei can also be used to compute $\eta^{2}, \varepsilon^{2}$, and $\omega^{2}$ for $F$ tests after an ANOVA. The following example from Smithson $(2001,623)$ illustrates the use of esizei for $\mathrm{df}_{\text {num }}=4, \mathrm{df}_{\mathrm{den}}=50$, and $F=4.2317$ :

```
. esizei 4 50 4.2317, level(90)
```

Effect sizes for linear models

| Effect size | Estimate | $[90 \%$ conf. interval] |  |
| ---: | :---: | :---: | :---: |
| Eta-squared | .2529151 | .0521585 | .3603621 |
| Epsilon-squared | .1931483 |  |  |
| Omega-squared | .1903049 |  |  |

## Video example

Tour of effect sizes

## Stored results

esize and esizei for comparing two means store the following in $r()$ :
Scalars

```
r(d)
    r(lb_d)
    r(ub_d)
    r(g)
    r(lb_g)
    r(ub_g)
    r(delta1)
    r(lb_delta1)
    r(ub_delta1)
    r(delta2)
    r(lb_delta2)
    r(ub_delta2)
    r(r_pb)
    r(lb_r_pb)
    r(ub_r_pb)
    r(N_1) sample size }\mp@subsup{n}{1}{

        lower confidence bound for Hedges's g
        upper confidence bound for Hedges's }
        Glass's }\Delta\mathrm{ for group 1
        lower confidence bound for Glass's }\Delta\mathrm{ for group 1
        upper confidence bound for Glass's }\Delta\mathrm{ for group 1
        Glass's }\Delta\mathrm{ for group 2
        lower confidence bound for Glass's }\Delta\mathrm{ for group 2
        upper confidence bound for Glass's }\Delta\mathrm{ for group 2
        point-biserial correlation coefficient
        lower confidence bound for the point-biserial correlation coefficient
        upper confidence bound for the point-biserial correlation coefficient
    confidence level
```

esizei for $F$ tests after ANOVA stores the following in r() :
Scalars

```
r(eta2) 渞
    r(lb_eta2) lower confidence bound for }\mp@subsup{\eta}{}{2
    r(ub_eta2) upper confidence bound for }\mp@subsup{\eta}{}{2
    r(epsilon2) & <
    r(omega2) }\mp@subsup{\omega}{}{2
    r(level) confidence level
```

## Methods and formulas

For the $d$ family, the effect-size parameter of interest is the scaled difference between the means given by

$$
\delta=\frac{\left(\mu_{1}-\mu_{2}\right)}{\sigma}
$$

One of the most popular estimators of effect size is Cohen's $d$, given by

$$
\text { Cohen's } d=\frac{\left(\bar{x}_{1}-\bar{x}_{2}\right)}{s^{*}}
$$

where

$$
s^{*}=\sqrt{\frac{\left(n_{1}-1\right) s_{1}^{2}+\left(n_{2}-1\right) s_{2}^{2}}{n_{1}+n_{2}-2}}
$$

Hedges (1981) showed that Cohen's $d$ is biased and proposed the unbiased estimator

$$
\text { Hedges's } g=\text { Cohen's } d \times c(m)
$$

where $m=n_{1}+n_{2}-2$ and

$$
c(m)=\frac{\Gamma\left(\frac{m}{2}\right)}{\sqrt{\frac{m}{2}} \Gamma\left(\frac{m-1}{2}\right)}
$$

Glass (Smith and Glass 1977) proposed an estimator for $\delta$ in the context of designed experiments,

$$
\text { Glass's } \Delta=\frac{\left(\bar{x}_{\text {treated }}-\bar{x}_{\text {control }}\right)}{s_{\text {control }}}
$$

where $s_{\text {control }}$ is the standard deviation for the control group.
As noted above, esize and esizei report two estimates of Glass's $\Delta$ : one using the standard deviation for group 1 and the other using the standard deviation for group 2 :

$$
\text { Glass's } \Delta_{1}=\frac{\left(\bar{x}_{1}-\bar{x}_{2}\right)}{s_{1}}
$$

and

$$
\text { Glass's } \Delta_{2}=\frac{\left(\bar{x}_{1}-\bar{x}_{2}\right)}{s_{2}}
$$

For the $r$ family, the effect-size parameter of interest is the ratio of the variance attributable to an effect and the total variance:

$$
\eta^{2}=\frac{\sigma_{\text {effect }}^{2}}{\sigma_{\text {total }}^{2}}
$$

A popular estimator of $\eta$ when there are two groups is the point-biserial correlation coefficient,

$$
r_{\mathrm{PB}}=\frac{t}{\sqrt{t^{2}+\mathrm{df}}}
$$

where $t$ is the $t$ statistic for the difference between the means of the two groups, and $d f$ is the corresponding degrees of freedom. Satterthwaite's or Welch's adjustment (see [R] ttest for details) to the degrees of freedom can be used to calculate $r_{\mathrm{PB}}$ by specifying the unequal or welch option, respectively.

When more than two means are being compared, as in the case of an ANOVA with $p$ groups, a popular estimator of effect size is the correlation ratio denoted $\eta^{2}$ (Fisher 1925; Kerlinger and Lee 2000). $\eta^{2}$ can be computed directly as the ratio of the $\mathrm{SS}_{\text {effect }}$ and the $\mathrm{SS}_{\text {total }}$ or as a function of the $F$ statistic with numerator degrees of freedom equal to $\mathrm{df}_{\text {num }}$ and denominator degrees of freedom equal to $\mathrm{df}_{\text {den }}$.

$$
\widehat{\eta}^{2}=\frac{F}{F+\mathrm{df}_{\mathrm{den}} / \mathrm{df}_{\mathrm{num}}}
$$

Like its equivalent estimator $R^{2}, \eta^{2}$ has an upward bias. Less biased estimators of effect size are $\varepsilon^{2}$ and $\omega^{2}$ (Grissom and Kim 2012).

$$
\widehat{\varepsilon}^{2}=\frac{F-1}{F+\mathrm{df}_{\mathrm{den}} / \mathrm{df}_{\text {num }}}=\widehat{\eta}^{2}-\frac{\mathrm{df}_{\text {num }}}{\mathrm{df}_{\mathrm{den}}}\left(1-\widehat{\eta}^{2}\right)
$$

$$
\widehat{\omega}^{2}=\frac{F-1}{F+\left(\mathrm{df}_{\mathrm{den}}+1\right) / \mathrm{df}_{\mathrm{num}}}
$$

To calculate $\widehat{\eta}^{2}, \widehat{\varepsilon}^{2}$, and $\widehat{\omega}^{2}$ directly after anova or regress, see estat esize in $[\mathrm{R}]$ regress postestimation.

Cohen's $d$, Hedges's $g$, and Glass's $\Delta$ have been shown to have a noncentral $t$ distribution (Hedges 1981) with noncentrality parameter equal to

$$
\lambda=\delta \sqrt{\frac{n_{1} n_{2}}{n_{1}+n_{2}}}
$$

Confidence intervals are calculated by finding the noncentrality parameters $\lambda_{\text {lower }}$ and $\lambda_{\text {upper }}$ that correspond to

$$
\operatorname{Pr}\left(\mathrm{df}, \delta, \lambda_{\text {lower }}\right)=1-\frac{\alpha}{2}
$$

and

$$
\operatorname{Pr}\left(\mathrm{df}, \delta, \lambda_{\text {upper }}\right)=\frac{\alpha}{2}
$$

using the function npnt ( $d f, t, p$ ). The noncentrality parameters are then transformed back to the effect-size scale:

$$
\delta_{\text {lower }}=\lambda_{\text {lower }} \sqrt{\frac{n_{1}+n_{2}}{n_{1} n_{2}}}
$$

and

$$
\delta_{\text {upper }}=\lambda_{\text {upper }} \sqrt{\frac{n_{1}+n_{2}}{n_{1} n_{2}}}
$$

(see Venables [1975]; Steiger and Fouladi [1997]; Cumming and Finch [2001]; Smithson [2001]).
Confidence intervals for the point-biserial correlation coefficient are calculated similarly and transformed back to the effect-size scale as

$$
r_{\text {lower }}=\frac{\lambda_{\text {lower }}}{\sqrt{\lambda_{\text {lower }}^{2}+\mathrm{df}}}
$$

and

$$
r_{\text {upper }}=\frac{\lambda_{\text {upper }}}{\sqrt{\lambda_{\text {upper }}^{2}+\mathrm{df}}}
$$

Following Smithson's (2001) notation, the $F$ statistic is written as

$$
F_{\mathrm{df}_{\mathrm{num}}, \mathrm{df}_{\mathrm{den}}}=f^{2}\left(\mathrm{df}_{\mathrm{num}} / \mathrm{df}_{\mathrm{den}}\right)
$$

This equation has a noncentral $F$ distribution with noncentrality parameter:

$$
\lambda=f^{2}\left(\mathrm{df}_{\mathrm{num}}+\mathrm{df}_{\mathrm{den}}+1\right)
$$

where $f^{2}=\eta^{2} /\left(1-\eta^{2}\right)$.

Confidence intervals for $\widehat{\eta}^{2}$ are calculated by finding the noncentrality parameters $\lambda_{\text {lower }}$ and $\lambda_{\text {upper }}$ for a noncentral $F$ distribution that correspond to

$$
\operatorname{Pr}\left(\mathrm{df}_{\text {num }}, \mathrm{df}_{\text {den }}, F, \lambda_{\text {lower }}\right)=1-\frac{\alpha}{2}
$$

and

$$
\operatorname{Pr}\left(\mathrm{df}_{\text {num }}, \mathrm{df}_{\text {den }}, F, \lambda_{\text {upper }}\right)=\frac{\alpha}{2}
$$

using the function $\operatorname{npnF}\left(d f_{1}, d f_{2}, f, p\right)$. The noncentrality parameters are transformed back to the $\widehat{\eta}^{2}$ scale as

$$
\widehat{\eta}_{\text {lower }}^{2}=\frac{\lambda_{\text {lower }}}{\lambda_{\text {lower }}+\mathrm{df}_{\text {num }}+\mathrm{df}_{\text {den }}+1}
$$

and

$$
\widehat{\eta}_{\text {upper }}^{2}=\frac{\lambda_{\text {upper }}}{\lambda_{\text {upper }}+\mathrm{df}_{\text {num }}+\mathrm{df}_{\text {den }}+1}
$$

While confidence intervals for $\widehat{\varepsilon}^{2}$ can be constructed using the same transformation that links it with $\widehat{\eta}^{2}$, there are several arguments for not using them in practice. See Smithson $(2003,54)$ for further details.

Fred Nichols Kerlinger (1910-1991) was born in New York City. He studied music at New York University and graduated magna cum laude with a degree in education and philosophy. After graduation, he joined the US Army and served as a counterintelligence officer in Japan in 1946. Kerlinger earned an MA and a PhD in educational psychology from the University of Michigan and held faculty appointments at several universities, including New York University. He was president of the American Educational Research Association and is best known for his popular and influential book Foundations of Behavioral Research (1964), which introduced Fisher's (1925) $\eta^{2}$ statistic to behavioral researchers.
William Lee Hays (1926-1995) was born in Clarksville, Texas. He studied mathematics and psychology at Paris Junior College in Paris, Texas, and at East Texas State College. He earned BS and MS degrees from North Texas State University. Upon completion of his PhD in psychology at the University of Michigan, he joined the faculty, where he eventually became associate vice president for academic affairs. In 1977, Hays accepted an appointment as vice president for academic affairs at the University of Texas at Austin, where he remained until his death in 1995. Hays is best known for his book Statistics for Psychologists (1963), which introduced the $\omega^{2}$ statistic (and is actually denoted here by $\varepsilon^{2}$ ).

## Title

estat - Postestimation statistics

Description Syntax

## Description

estat displays scalar- and matrix-valued statistics after estimation; it complements predict, which calculates variables after estimation. Exactly what statistics estat can calculate depends on the previous estimation command.

Three sets of statistics are so commonly used that they are available after all estimation commands that store the model log likelihood. estat ic displays Akaike's and Schwarz's Bayesian information criteria. estat summarize summarizes the variables used by the command and automatically restricts the sample to e (sample); it also summarizes the weight variable and cluster structure, if specified. estat vce displays the covariance or correlation matrix of the parameter estimates of the previous model.

## Syntax

Command Reference

## Options

$\qquad$ Main
all requests that the statistic be computed for all observations in the data, ignoring any if or in restrictions specified by the estimation command.
cutoff(\#) specifies the value for determining whether an observation has a predicted positive outcome. An observation is classified as positive if its predicted probability is $\geq \#$. The default is 0.5 .

## Remarks and examples

estat classification presents the classification statistics and classification table after logistic, logit, probit, or ivprobit.

Statistics are produced either for the estimation sample (the default) or for any set of observations. When weights, if, or in is used with the estimation command, it is not necessary to repeat the qualifier when you want statistics computed for the estimation sample. Specify if, in, or the all option only when you want statistics computed for a set of observations other than the estimation sample. Specify weights only when you want to use a different set of weights.

## - Example 1

We illustrate estat classification after logistic; see [R] logistic.

The overall rate of correct classification is estimated to be 73.54 , with $90.77 \%$ of the normal weight group correctly classified (specificity) and only $35.59 \%$ of the low weight group correctly classified (sensitivity). Classification is sensitive to the relative sizes of each component group, and always favors classification into the larger group. This phenomenon is evident here.

By default, estat classification uses a cutoff of 0.5 , although you can vary this with the cutoff() option. You can use the lsens command to review the potential cutoffs; see [R] Isens.

## Stored results

estat classification stores the following in $r()$ :
Scalars
$r$ (P_corr) percent correctly classified
$r\left(P \_p 1\right)$ sensitivity
$r\left(P \_n 0\right) \quad$ specificity
$r\left(P_{-} 0\right)$ false-positive rate given true negative
$r\left(P \_n 1\right) \quad$ false-negative rate given true positive
$r\left(P \_1 p\right) \quad$ positive predictive value
$r\left(P \_0 n\right) \quad$ negative predictive value
$r$ (P_Op) false-positive rate given classified positive
$r\left(P \_1 n\right) \quad$ false-negative rate given classified negative
Matrices
$r$ (ctable) classification table

## Methods and formulas

Let $j$ index observations. Define $c$ as the cutoff() specified by the user or, if not specified, as 0.5 . Let $p_{j}$ be the predicted probability of a positive outcome and $y_{j}$ be the actual outcome, which we will treat as 0 or 1 , although Stata treats it as 0 and non- 0 , excluding missing observations.

A prediction is classified as positive if $p_{j} \geq c$ and otherwise is classified as negative. The classification is correct if it is positive and $y_{j}=1$ or if it is negative and $y_{j}=0$.

Sensitivity is the fraction of $y_{j}=1$ observations that are correctly classified. Specificity is the percentage of $y_{j}=0$ observations that are correctly classified.

## Description

estat gof reports the Pearson goodness-of-fit test or the Hosmer-Lemeshow goodness-of-fit test.
estat gof requires that the current estimation results be from logistic, logit, or probit; see $[R]$ logistic, $[R]$ logit, or $[R]$ probit. For estat gof after poisson, see $[R]$ poisson postestimation. For estat gof after sem, see [SEM] estat gof.

## Quick start

Pearson goodness-of-fit test for current estimation results
estat gof
Same as above, but apply to all observations in dataset instead of just those in e(sample)
estat gof, all
Hosmer-Lemeshow goodness-of-fit test
estat gof, group(10)
Same as above, and display table of groups used for the test
estat gof, group(10) table

## Menu for estat

Statistics $>$ Postestimation

## Syntax

```
estat gof [if] [in] [weight] [, options]
```

options
Main
group(\#)
all
outsample
table

Description
perform Hosmer-Lemeshow goodness-of-fit test using \# quantiles execute test for all observations in the data
adjust degrees of freedom for samples outside estimation sample display table of groups used for test
estat gof is not appropriate with svy estimation results.
collect is allowed; see [U] 11.1.10 Prefix commands.
fweights are allowed; see [U] 11.1.6 weight.

## Options

## Main

group(\#) specifies the number of quantiles to be used to group the data for the Hosmer-Lemeshow goodness-of-fit test. group (10) is typically specified. If this option is not given, the Pearson goodness-of-fit test is computed using the covariate patterns in the data as groups.
all requests that the statistic be computed for all observations in the data, ignoring any if or in restrictions specified by the estimation command.
outsample adjusts the degrees of freedom for the Pearson and Hosmer-Lemeshow goodness-of-fit tests for samples outside the estimation sample. See Samples other than the estimation sample later in this entry.
table displays a table of the groups used for the Hosmer-Lemeshow or Pearson goodness-of-fit test with predicted probabilities, observed and expected counts for both outcomes, and totals for each group.

## Remarks and examples

Remarks are presented under the following headings:
Introduction
Samples other than the estimation sample

## Introduction

estat gof computes goodness-of-fit tests: either the Pearson $\chi^{2}$ test or the Hosmer-Lemeshow test.

By default, estat gof computes statistics for the estimation sample by using the last model fit by logistic, logit, or probit. However, samples other than the estimation sample can be specified; see Samples other than the estimation sample later in this entry.

## > Example 1

estat gof, typed without options, presents the Pearson $\chi^{2}$ goodness-of-fit test for the fitted model. The Pearson $\chi^{2}$ goodness-of-fit test is a test of the observed against expected number of responses using cells defined by the covariate patterns; see predict with the number option in $[\mathrm{R}]$ logistic postestimation for the definition of covariate patterns.

```
. use https://www.stata-press.com/data/r18/lbw
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
    (output omitted)
. estat gof
Goodness-of-fit test after logistic model
Variable: low
    Number of observations = 189
Number of covariate patterns = 182
    Pearson chi2(173) = 179.24
                        Prob > chi2 = 0.3567
```

Our model fits reasonably well. However, the number of covariate patterns is close to the number of observations, making the applicability of the Pearson $\chi^{2}$ test questionable but not necessarily inappropriate. Hosmer, Lemeshow, and Sturdivant (2013, 157-160) suggest regrouping the data by ordering on the predicted probabilities and then forming, say, 10 nearly equal-sized groups. estat gof with the group() option does this:

```
. estat gof, group(10)
note: obs collapsed on 10 quantiles of estimated probabilities.
Goodness-of-fit test after logistic model
Variable: low
    Number of observations = 189
    Number of groups = 10
Hosmer-Lemeshow chi2(8) = 9.65
        Prob > chi2 = 0.2904
```

Again we cannot reject our model. If we specify the table option, estat gof displays the groups along with the expected and observed number of positive responses (low-birthweight babies):
. estat gof, group(10) table
note: obs collapsed on 10 quantiles of estimated probabilities.
Goodness-of-fit test after logistic model
Variable: low
Table collapsed on quantiles of estimated probabilities

| Group | Prob | Obs_1 | Exp_1 | Obs_0 | Exp_0 | Total |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 0.0827 | 0 | 1.2 | 19 | 17.8 | 19 |
| 2 | 0.1276 | 2 | 2.0 | 17 | 17.0 | 19 |
| 3 | 0.2015 | 6 | 3.2 | 13 | 15.8 | 19 |
| 4 | 0.2432 | 1 | 4.3 | 18 | 14.7 | 19 |
| 5 | 0.2792 | 7 | 4.9 | 12 | 14.1 | 19 |
| 6 | 0.3138 | 7 | 5.6 | 12 | 13.4 | 19 |
| 7 | 0.3872 | 6 | 6.5 | 13 | 12.5 | 19 |
| 8 | 0.4828 | 7 | 8.2 | 12 | 10.8 | 19 |
| 9 | 0.5941 | 10 | 10.3 | 9 | 8.7 | 19 |
| 10 | 0.8391 | 13 | 12.8 | 5 | 5.2 | 18 |

Number of observations $=$
Number of groups $=$
Hosmer-Lemeshow chi2(8) $=$
Prob > chi2 $=0.2904$

In this table, the column Prob shows the upper boundaries of predicted probabilities for these 10 groups, which are the 10 th, 20 th, $\ldots$, and 100 th percentiles in this case.

## - Technical note

estat gof with the group() option puts all observations with the same predicted probabilities into the same group. If, as in the previous example, we request 10 groups, the groups that estat gof makes are $\left[p_{0}, p_{10}\right],\left(p_{10}, p_{20}\right],\left(p_{20}, p_{30}\right], \ldots,\left(p_{90}, p_{100}\right]$, where $p_{k}$ is the $k$ th percentile of the predicted probabilities, with $p_{0}$ the minimum and $p_{100}$ the maximum.

If there are many ties at the quantile boundaries, as will often happen if all independent variables are categorical and there are only a few of them, the sizes of the groups will be uneven. If the totals in some of the groups are small, the $\chi^{2}$ statistic for the Hosmer-Lemeshow test may be unreliable. In this case, fewer groups should be specified, or the Pearson goodness-of-fit test may be a better choice.

## > Example 2

The table option can be used without the group() option. We would not want to specify this for our current model because there were 182 covariate patterns in the data, caused by including the two continuous variables, age and lwt, in the model. As an aside, we fit a simpler model and specify table with estat gof:
. logistic low i.race smoke ui
Logistic regression
Number of obs = 189
LR chi2 (4) $=18.80$
Prob > chi2 $=0.0009$

Number of observations $=189$
Number of covariate patterns $=11$
Pearson chi2 (6) $=5.71$
Prob > chi2 $=0.4569$

- Technical note
logistic, logit, or probit and estat gof keep track of the estimation sample. If you type, for instance, logistic ... if $x==1$, then when you type estat gof, the statistics will be calculated on the $x==1$ subsample of the data automatically.

You should specify if or in with estat gof only when you wish to calculate statistics for a set of observations other than the estimation sample. See Samples other than the estimation sample later in this entry.

If the logistic model was fit with fweights, estat gof properly accounts for the weights in its calculations. (estat gof allows only fweights.) You do not have to specify the weights when you run estat gof. Weights should be specified with estat gof only when you wish to use a different set of weights.

## Samples other than the estimation sample

estat gof can be used with samples other than the estimation sample. By default, estat gof remembers the estimation sample used with the last logistic, logit, or probit command. To override this, simply use an if or in restriction to select another set of observations, or specify the all option to force the command to use all the observations in the dataset.

If you use estat gof with a sample that is completely different from the estimation sample (that is, no overlap), you should also specify the outsample option so that the $\chi^{2}$ statistic properly adjusts the degrees of freedom upward. For an overlapping sample, the conservative thing to do is to leave the degrees of freedom the same as they are for the estimation sample.

## > Example 3

We want to develop a model for predicting low-birthweight babies. One approach would be to divide our data into two groups, a developmental sample and a validation sample. See Lemeshow and Gall (1994) and Tilford, Roberson, and Fiser (1995) for more information on developing prediction models and severity-scoring systems.

We will do this with the low-birthweight data that we considered previously. First, we randomly divide the data into two samples.

```
. use https://www.stata-press.com/data/r18/lbw, clear
(Hosmer & Lemeshow data)
. set seed 101
. generate r = runiform()
. sort r
. generate group = 1 if _n <= _N/2
(95 missing values generated)
. replace group = 2 if group==.
(95 real changes made)
```

Then, we fit a model using the first sample (group $=1$ ), which is our developmental sample.

```
. logistic low age lwt i.race smoke ptl ht ui if group==1
```

Logistic regression $\quad$ Number of obs $=\quad 94$
LR chi2(8) $=28.03$
Prob > chi2 $=0.0005$
Log likelihood $=-42.351112$
Pseudo R2 $=0.2487$

| low | Odds ratio | Std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| age | .922865 | .0555349 | -1.33 | 0.182 | .8201924 | 1.03839 |
| lwt | .9825782 | .0114438 | -1.51 | 0.131 | .9604029 | 1.005265 |
| race |  |  |  |  |  |  |
| Black | 5.975476 | 4.936135 | 2.16 | 0.030 | 1.183652 | 30.16621 |
| Other | 3.364479 | 2.760784 | 1.48 | 0.139 | .6736724 | 16.803 |
|  |  |  |  |  |  |  |
| smoke | 3.442716 | 2.53779 | 1.68 | 0.094 | .8117831 | 14.60032 |
| ptl | 3.467274 | 2.337648 | 1.84 | 0.065 | .9249222 | 12.99784 |
| ht | 5.928512 | 6.047106 | 1.74 | 0.081 | .8030021 | 43.76982 |
| ui | 4.045883 | 2.947396 | 1.92 | 0.055 | .9703295 | 16.8697 |
| _cons | 3.120871 | 5.977489 | 0.59 | 0.552 | .0731049 | 133.231 |

Note: _cons estimates baseline odds.
To test calibration in the developmental sample, we calculate the Hosmer-Lemeshow goodness-of-fit test by using estat gof.

```
. estat gof, group(10)
note: obs collapsed on 10 quantiles of estimated probabilities.
Goodness-of-fit test after logistic model
Variable: low
    Number of observations = 94
    Number of groups = 10
Hosmer-Lemeshow chi2(8) = 5.64
        Prob > chi2 = 0.6871
```

We did not specify an if statement with estat gof because we wanted to use the estimation sample. Because the test is not significant, we are satisfied with the fit of our model.

Running lroc (see [R] lroc) gives a measure of the discrimination:

```
. lroc, nograph
Logistic model for low
Number of observations = 94
Area under ROC curve = 0.8145
```

Now, we test the calibration of our model by performing a goodness-of-fit test on the validation sample. We specify the outsample option so that the number of degrees of freedom is 10 rather than 8 .
. estat gof if group $==2$, group (10) table outsample
note: obs collapsed on 10 quantiles of estimated probabilitie
Goodness-of-fit test after logistic model
Variable: low
Table collapsed on quantiles of estimated probabilities

| Group | Prob | Obs_1 | Exp_1 | Obs_0 | Exp_0 | Total |

| 7 | 0.4190 | 3 | 3.6 | 7 | 6.4 | 10 |
| 8 | 0.5248 | 5 | 4.3 | 4 | 4.7 | 9 |
| 9 | 0.6413 | 5 | 5.8 | 5 | 4.2 | 10 |
| 10 | 0.9787 | 4 | 7.3 | 5 | 1.7 | 9 |

Number of observations $=95$
Number of groups $=10$
Hosmer-Lemeshow chi2(10) $=29.30$
Prob $>$ chi2 $=0.0011$
We must acknowledge that our model does not fit well on the validation sample. The model's discrimination in the validation sample is appreciably lower, as well.
. lroc if group==2, nograph
Logistic model for low
Number of observations $=95$
Area under ROC curve $=0.6835$

## Stored results

estat gof stores the following in r() :
Scalars

```
r(N) number of observations
    r(m) number of covariate patterns or groups
    r(df) degrees of freedom
    r(chi2) < < 
    r(p) p-value for }\mp@subsup{\chi}{}{2}\mathrm{ test
```

## Methods and formulas

Let $M$ be the total number of covariate patterns among the $N$ observations. View the data as collapsed on covariate patterns $j=1,2, \ldots, M$, and define $m_{j}$ as the total number of observations having covariate pattern $j$ and $y_{j}$ as the total number of positive responses among observations with covariate pattern $j$. Define $p_{j}$ as the predicted probability of a positive outcome in covariate pattern $j$.

The Pearson $\chi^{2}$ goodness-of-fit statistic is

$$
\chi^{2}=\sum_{j=1}^{M} \frac{\left(y_{j}-m_{j} p_{j}\right)^{2}}{m_{j} p_{j}\left(1-p_{j}\right)}
$$

This $\chi^{2}$ statistic has approximately $M-k$ degrees of freedom for the estimation sample, where $k$ is the number of independent variables, including the constant. For a sample outside the estimation sample, the statistic has $M$ degrees of freedom.

The Hosmer-Lemeshow goodness-of-fit $\chi^{2}$ (Hosmer and Lemeshow 1980; Lemeshow and Hosmer 1982; Hosmer, Lemeshow, and Klar 1988) is calculated similarly, except that rather than using the $M$ covariate patterns as the group definition, the quantiles of the predicted probabilities are used to form groups. Let $G=$ \# be the number of quantiles requested with group (\#). The smallest index $1 \leq q(i) \leq M$, such that

$$
W_{q(i)}=\sum_{j=1}^{q(i)} m_{j} \geq \frac{N}{G}
$$

gives $p_{q(i)}$ as the upper boundary of the $i$ th quantile for $i=1,2, \ldots, G$. Let $q(0)=1$ denote the first index.

The groups are then

$$
\left[p_{q(0)}, p_{q(1)}\right],\left(p_{q(1)}, p_{q(2)}\right], \ldots,\left(p_{q(G-1)}, p_{q(G)}\right]
$$

If the table option is given, the upper boundaries $p_{q(1)}, \ldots, p_{q(G)}$ of the groups appear next to the group number on the output.

The resulting $\chi^{2}$ statistic has approximately $G-2$ degrees of freedom for the estimation sample. For a sample outside the estimation sample, the statistic has $G$ degrees of freedom.

Display AIC, BIC, AICc, and CAIC
estat ic, all
Specify $N$ to be used in calculating BIC as 500
estat ic, n(500)
Specify $N$ and degrees of freedom to be used in calculating all information criteria as 500 and 10 , respectively
estat ic, $n(500) d f(10)$ all

## Menu for estat

Statistics $>$ Postestimation

## Syntax

estat ic [, options]
options Description

| aiccorrected | report AICc instead of AIC <br> report CAIC instead of AIC |
| :--- | :--- |
| aicconsistent | report all four information criteria: AIC, BIC, AICc, and CAIC <br> all <br> $\mathrm{n}(\#)$ |
|  | specify $N$ to be used in calculating BIC, AICc, and CAIC; <br> see $[R]$ IC note |
| specify degrees of freedom $k$ to be used in calculating AIC, BIC, |  |
| AICc, and CAIC |  |

collect is allowed; see [U] 11.1.10 Prefix commands.

## Options

aiccorrected specifies that AICc be computed instead of AIC. This information criterion is a second-order approximation and is recommended for small sample sizes.

Only one of aiccorrected, aicconsistent, or all is allowed.
aicconsistent specifies that CAIC be computed instead of AIC. This information criterion is a consistent version of AIC; that is, the probability of selecting the "true model" approaches 1 as sample size increases.

Only one of aicconsistent, aiccorrected, or all is allowed.
all produces a table showing all four information criteria: AIC, BIC, AICc, and CAIC.
Only one of all, aiccorrected, or aicconsistent is allowed.
$\mathrm{n}(\#)$ specifies $N$ to be used in calculating BIC, AICc, and CAIC; see [R] IC note.
$\mathrm{df}(\#)$ specifies degrees of freedom $k$ to be used in calculating AIC, BIC, AICc, and CAIC. By default, $k$ is the number of estimated parameters.

## Remarks and examples

estat ic calculates four information criteria used to compare models fit to the same dataset. Unlike likelihood-ratio, Wald, and similar testing procedures, the models need not be nested to compare the information criteria. The information criteria are constructed as a function of the log likelihood $\ln L$, the number of estimated parameters (degrees of freedom) $k$, and, in some cases, the number of observations $N$. Because they are based on the log-likelihood function, information criteria are available only after commands that report the log likelihood.

The use of information criteria is subjective, and no formal inference can be drawn from the reported values. In a typical approach, a set of potential models is selected, and a superior model is selected from the values of information criteria. A superior model is the model with the lowest value of information criterion. For example, given two models, the model with the lowest AIC fits the data better than the model with the larger AIC. For details, see Methods and formulas.

## $>$ Example 1

In [R] mlogit, we fit a model explaining the type of insurance a person has on the basis of age, gender, race, and site of study. Here we refit the model with and without the site dummies and compare the models.

```
. use https://www.stata-press.com/data/r18/sysdsn1
(Health insurance data)
. mlogit insure age male nonwhite
    (output omitted)
. estat ic
Akaike's information criterion and Bayesian information criterion
```

| Model | N | ll (null) | ll(model) | df | AIC | BIC |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| . | 615 | -555.8545 | -545.5833 | 8 | 1107.167 | 1142.54 |

Note: BIC uses $N$ = number of observations. See [R] IC note.
. mlogit insure age male nonwhite i.site
(output omitted)
. estat ic
Akaike's information criterion and Bayesian information criterion

| Model | N | ll (null) | ll(model) | df | AIC | BIC |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| . | 615 | -555.8545 | -534.3616 | 12 | 1092.723 | 1145.783 |

Note: BIC uses $N=$ number of observations. See [R] IC note.
The AIC indicates that the model including the site dummies fits the data better, whereas BIC indicates the opposite. As is often the case, different model-selection criteria have led to conflicting conclusions.

## > Example 2

In example 1, we compared AIC and BIC. Here we focus on comparing AIC and AICc for small sample size. For simplicity, we are using the same health insurance dataset but running mlogit with the age $<30$ condition to reduce the sample size.

```
. mlogit insure age male nonwhite if age < 30
    (output omitted)
. estat ic, all
Information criteria
```

| Model | N | ll(null) | ll(model) | df |
| ---: | ---: | ---: | ---: | ---: |
| $\cdot$ | 87 | -76.93025 | -70.36684 | 8 |

Note: BIC, AICc, and CAIC use $N=$ number of observations.
See [R] IC note.

| Model | AIC | BIC | AICc | CAIC |
| ---: | ---: | ---: | ---: | ---: |
| . | 156.7337 | 176.4609 | 158.5798 | 184.4609 |

Legend: AIC is Akaike's information criterion.
BIC is Bayesian information criterion.
AICc is corrected Akaike's information criterion.
CAIC is consistent Akaike's information criterion.
. mlogit insure age male nonwhite i.site if age < 30
(output omitted)
. estat ic, all
Information criteria

| Model | N | ll(null) | ll(model) | df |
| ---: | ---: | ---: | ---: | ---: |
| . | 87 | -76.93025 | -66.03298 | 12 |

Note: BIC, AICc, and CAIC use $N=$ number of observations.
See [R] IC note.

| Model | AIC | BIC | AICc | CAIC |
| ---: | ---: | ---: | ---: | ---: |
| . | 156.066 | 185.6569 | 160.2822 | 197.6569 |

Legend: AIC is Akaike's information criterion.
BIC is Bayesian information criterion.
AICc is corrected Akaike's information criterion.
CAIC is consistent Akaike's information criterion.
Burnham and Anderson (2002) recommend using AICc when the ratio $N / k<40$. The AIC suggests that the model with the site dummies is preferred, whereas AICc reports the opposite result.

## Example 3

As we discuss in the technical note below, for the linear mixed models fit using restricted maximum likelihood (REML), one needs to be careful when comparing models using the standard information criteria, especially when the fixed-effects specifications differ across models. In this example, we show how to use $\mathrm{n}(\#)$ and $\mathrm{df}(\#)$ to modify the the standard $N$ and $k$ used in the information criteria
when we compare such models. As in [ME] mixed, we consider the dataset from Munnell (1990) and estimate a Cobb-Douglas production function, which examines the productivity of public capital in each state's private output (Baltagi, Song, and Jung 2001).

Suppose we want to compare two models:

```
. use https://www.stata-press.com/data/r18/productivity
(Public capital productivity)
. mixed gsp private emp hwy water other unemp || region: || state:, reml
    (output omitted)
. estimates store model1
. mixed gsp private emp hwy unemp || region: hwy || state: unemp, reml
    (output omitted)
. estimates store model2
```

The two models differ in both their fixed-effects and random-effects specifications. By default, the number of degrees of freedom in estat ic is calculated as $k=k_{f}+k_{r}$, where $k_{f}$ and $k_{r}$ are the number of estimated fixed-effects and random-effects parameters, respectively. For REML, Gurka (2006) evaluates the performance of various information criteria. He discusses using $k=k_{r}$ and different possible values for $N$. Here, we follow the Vonesh and Chinchilli (1997) approach and choose $N-k_{f}$. Finally, we run estat ic to compare the models:

```
. estimates restore model1
(results model1 are active now)
. estat ic, n(809) df(3)
Akaike's information criterion and Bayesian information criterion
```

| Model | N | ll (null) | ll(model) | df | AIC | BIC |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| model1 | 809 |  | 1404.71 | 3 | -2803.42 | -2789.333 |

. estimates restore model2
(results model2 are active now)
. estat ic, $\mathrm{n}(811) \mathrm{df}(5)$

Akaike's information criterion and Bayesian information criterion

| Model | N | ll (null) | ll(model) | df | AIC | BIC |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| model2 | 811 |  | 1413.557 | 5 | -2817.114 | -2793.623 |

Both AIC and BIC indicate that the second model is preferable.

## - Technical note

glm and binreg, ml report a slightly different version of AIC and BIC; see [R] glm for the formulas used. That version is commonly used within the generalized linear models literature; see, for example, Hardin and Hilbe (2018). The literature on information criteria is vast; see, among others, Akaike (1973), Sawa (1978), and Raftery (1995). Judge et al. (1985) discuss the use of information criteria in econometrics. Royston and Sauerbrei (2008, chap. 2) examine the use of information criteria as an alternative to stepwise procedures for selecting model variables.

For linear mixed models, when restricted maximum likelihood is used, the information criteria with default degrees of freedom and the number of observations cannot be used to compare models with varying sets of fixed effects, because the likelihood of restricted maximum likelihood is dependent on the fixed-effects design matrix (Harville 1974; Gurka 2006). By default, the degrees of freedom in estat ic is the sum of the dimension of fixed-effect parameters and the number of covariance parameters. Therefore, only models with the same sets of fixed effects can be compared. However, for each model, the $\mathrm{df}(\#)$ option can be specified manually to allow comparison with different sets of fixed effects. There are also different views on which number should be used as $N$ to calculate BIC, AICc, and CAIC. For example, see Vonesh and Chinchilli (1997) and Kass and Raftery (1995). Use the n (\#) option to pass a desired number of observations to the estat ic command. For details, see [R] IC note.

## Stored results

estat ic stores the following in $r()$ :
Matrices
$r(S) \quad$ row vector with columns (N, 11 (null), 11 (model), df, and information criteria)

## Methods and formulas

There are two main large-sample notions of information criteria: efficiency and consistency (Burnham and Anderson 2002). Efficient criteria target the best finite dimension model under the assumption that the unknown "true model" has infinite dimension. In contrast, assuming that the true data-generating model is finite and fixed, the consistent criterion selects the correct model with probability approaching 1 as $N \rightarrow \infty$. The AIC and AICc belong to the efficient class, while the BIC and CAIC to the consistent class.

Akaike's (1974) information criterion is defined as

$$
\mathrm{AIC}=-2 \ln L+2 k
$$

where $\ln L$ is the maximized $\log$-likelihood of the model and $k$ is the number of parameters estimated. Some authors define AIC as the expression above divided by the sample size.

AIC performs poorly when there are too many parameters in relation to the sample size. Hurvich and Tsai (1989) derived a second-order variant of AIC called AICc,

$$
\mathrm{AICc}=\mathrm{AIC}+\frac{2 k(k+1)}{N-k-1}
$$

where $N$ is the sample size. See $[\mathrm{R}]$ IC note for additional information on calculating and interpreting $N$. Compared with AIC, AICc has an additional bias-correction term, and for large $N$ and small $k$, this term is negligible. Burnham and Anderson (2002) recommend using AICc when the ratio $N / k<40$.

Schwarz's (1978) Bayesian information criterion is another measure of fit defined as

$$
\mathrm{BIC}=-2 \ln L+k \ln N
$$

Bozdogan (1987) proposed a consistent version of AIC called CAIC,

$$
\mathrm{CAIC}=-2 \ln L+k(\ln N+1)
$$

Burnham and Anderson (2002, chap. 6) argue that employing and comparing consistent and efficient information criteria in the same situation contrasts with the fact that they were designed to answer different questions. Thus, one needs to be careful when interpreting the results.

Hirotugu Akaike (1927-2009) was born in Fujinomiya City, Shizuoka Prefecture, Japan. He was the son of a silkworm farmer. He gained BA and DSc degrees from the University of Tokyo. Akaike's career from 1952 at the Institute of Statistical Mathematics in Japan culminated in service as Director General; after 1994, he was Professor Emeritus. His best-known work in a prolific career is on what is now known as the Akaike information criterion (AIC), which was formulated to help selection of the most appropriate model from a number of candidates.

Gideon E. Schwarz (1933-2007) was a professor of statistics at the Hebrew University, Jerusalem. He was born in Salzburg, Austria, and obtained an MSc in 1956 from the Hebrew University and a PhD in 1961 from Columbia University. His interests included stochastic processes, sequential analysis, probability, and geometry. He is best known for the Bayesian information criterion (BIC).

## Title

estat summarize - Summarize estimation sample

| Description | Quick start | Menu for estat | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Also see |

## Description

estat summarize summarizes the variables used by the command and automatically restricts the sample to the estimation sample; it also summarizes the weight variable and cluster structure, if specified.

## Quick start

Summary statistics for all variables in the model using estimation sample
estat summarize
Add variable labels to output
estat summarize, labels
Obtain summary of estimation sample for each equation
estat summarize, equation
Ignore weights when calculating summary statistics after weighted estimation
estat summarize, noweights

## Menu for estat

Statistics > Postestimation

## Syntax

estat summarize [eqlist] [, estat_summ_options]
estat_summ_options Description

| equation | display summary by equation <br> display summary by group; only after sem and gsem |
| :--- | :--- |
| group | display variable labels |
| nobels | suppress the header <br> noheader |
| ignore weights |  |
| coneights | control row spacing, line width, display of omitted variables <br> and base and empty cells, and factor-variable labeling |

eqlist is rarely used and specifies the variables, with optional equation name, to be summarized. eqlist may be varlist or (eqname ${ }_{1}$ : varlist) (eqname ${ }_{2}$ : varlist) .... varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.
collect is allowed; see [U] 11.1.10 Prefix commands.

## Options

equation requests that the dependent variables and the independent variables in the equations be displayed in the equation-style format of estimation commands, repeating the summary information about variables entered in more than one equation.
group displays summary information separately for each group. group is only allowed after sem or gsem with a group() variable specified.
labels displays variable labels.
noheader suppresses the header.
noweights ignores the weights, if any, from the previous estimation command. The default when weights are present is to perform a weighted summarize on all variables except the weight variable itself. An unweighted summarize is performed on the weight variable.
display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), and fvwrapon(style); see [R] Estimation options.

## Remarks and examples

Often when fitting a model, you will also be interested in obtaining summary statistics, such as the sample means and standard deviations of the variables in the model. estat summarize makes this process simple. The output displayed is similar to that obtained by typing

```
. summarize varlist if e(sample)
```

without the need to type the varlist containing the dependent and independent variables.

## $>$ Example 1

Continuing with the example in $[\mathrm{R}]$ estat ic, here we summarize the variables by using estat summarize.

| mlogit insure (output omitted) <br> estat summari <br> Estimation sa | ale nonwh <br> omitted <br> logit | i.site |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Variable | Mean | Std. dev. | Min | Max |
| insure | 1.596748 | . 6225846 | 1 | 3 |
| age | 44.46832 | 14.18523 | 18.11087 | 86.07254 |
| male | . 2504065 | . 4335998 | 0 | 1 |
| nonwhite | . 196748 | . 3978638 | 0 | 1 |
| site |  |  |  |  |
| 2 | . 3707317 | . 4833939 | 0 | 1 |
| 3 | . 3138211 | . 4644224 | 0 | 1 |

The output in the previous example contains all the variables in one table, though mlogit presents its results in a multiple-equation format. For models in which the same variables appear in all equations, that is fine; but for other multiple-equation models, we may prefer to have the variables separated by the equation in which they appear. The equation option makes this possible.

## > Example 2

Systems of simultaneous equations typically have different variables in each equation, and the equation option of estat summarize is helpful in such situations. In example 2 of $[R]$ reg3, we have a model of supply and demand. We first refit the model and then call estat summarize.

The first block of the table contains statistics on the dependent (or, more accurately, left-hand-side) variables, and because we specified quantity as the left-hand-side variable in both equations, it is listed twice. The second block refers to the variables in the first equation we specified, which we labeled "Demand" in our call to reg3; and the final block refers to the supply equation.

## Stored results

estat summarize stores the following in $r()$ :
Scalars
r(N_groups) number of groups (group only)
Matrices
r (stats) $\quad k \times 4$ matrix of means, standard deviations, minimums, and maximums
$\mathrm{r}($ stats [ \# $]$ ) $\left.\quad \begin{array}{c}k \times 4 \text { matrix } \\ \text { only }\end{array}\right)$ of means, standard deviations, minimums, and maximums for group \# (group

## Also see

## Title

estat vce - Display covariance matrix estimates

| Description | Quick start | Menu for estat | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Also see |

## Description

estat vce displays the covariance or correlation matrix of the parameter estimates of the previous model.

## Quick start

Display variance-covariance matrix of the estimates (VCE) from the previous model

> estat vce

Matrix of correlations rather than covariances
estat vce, correlation
Same as above, but report correlations using three decimal places
estat vce, correlation format(\%6.3f)
After fitting a multiple-equation model, display VCE for each equation in separate blocks
estat vce, block
Show VCE for equation y1 only
estat vce, equation(y1)

## Menu for estat

Statistics $>$ Postestimation

## Syntax

```
    estat vce [, estat_vce_options]
```

estat_vce_options Description

| covariance | display as covariance matrix; the default <br> display as correlation matrix |
| :--- | :--- |
| correlation | display only specified equations |
| equation $($ spec $)$ | display submatrices by equation <br> block |
| display submatrices by equation; diagonal blocks only |  |
| diarmat $(\%$ fint $)$ | display format for covariances and correlations |
| nolines | suppress lines between equations <br> control display of omitted variables and base and empty cells |

collect is allowed; see [U] 11.1.10 Prefix commands.

## Options

covariance displays the matrix as a variance-covariance matrix; this is the default.
correlation displays the matrix as a correlation matrix rather than a variance-covariance matrix. rho is a synonym.
equation (spec) selects part of the VCE to be displayed. If spec is eqlist, the VCE for the listed equations is displayed. If spec is eqlistl $\backslash$ eqlist 2 , the part of the VCE associated with the equations in eqlistl (rowwise) and eqlist 2 (columnwise) is displayed. If $s p e c$ is $*$, all equations are displayed. equation() implies block if diag is not specified.
block displays the submatrices pertaining to distinct equations separately.
diag displays the diagonal submatrices pertaining to distinct equations separately.
format (\% fint) specifies the number format for displaying the elements of the matrix. The default is format ( $\% 10.0 \mathrm{~g}$ ) for covariances and format (\%8.4f) for correlations. See [U] 12.5 Formats: Controlling how data are displayed for more information.
nolines suppresses lines between equations.
display_options: noomitted, noemptycells, baselevels, allbaselevels; see [R] Estimation options.

## Remarks and examples

estat vce allows you to display the VCE of the parameters of the previously fit model, as either a covariance matrix or a correlation matrix.
> Example 1
Returning to the example in $[\mathrm{R}]$ estat ic, here we display the covariance matrix of the parameters of the mlogit model by using estat vce.

| mlogit insure age male nonwhite (output omitted) |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |

| ---: | ---: | ---: | ---: | ---: |
| age | .00013022 |  |  |  |
| male | -.00050406 | .13248095 |  |  |
| nonwhite | -.00026145 | .01505449 | .16861327 |  |
| _cons | -.00562159 | -.01686629 | -.02474852 | .28607591 |

The block option is particularly useful for multiple-equation estimators. The first block of output here corresponds to the VCE of the estimated parameters for the first equation-the square roots of the diagonal elements of this matrix are equal to the standard errors of the first equation's parameters. Similarly, the final block corresponds to the VCE of the parameters for the second equation. The middle block shows the covariances between the estimated parameters of the first and second equations.

## Stored results

estat vce stores the following in r() :
Matrices
$r(V) \quad V C E$ or correlation matrix

## Also see

[R] estat - Postestimation statistics
$[\mathrm{R}]$ estat ic - Display information criteria
[R] estat summarize - Summarize estimation sample

## Title

estimates - Save and manipulate estimation results

Description Syntax Remarks and examples Also see

## Description

estimates allows you to store and manipulate estimation results:

- You can save estimation results in a file for use in later sessions.
- You can store estimation results in memory so that you can
a. switch among separate estimation results and
b. form tables combining separate estimation results.

## Syntax

| Command | Reference |
| :--- | :--- |
| Save and use results from disk <br> estimates save filename | $[\mathrm{R}]$ estimates save |
| $\underline{\text { estimates use filename }}$ | $[\mathrm{R}]$ estimates save |
| estimates describe using filename | $[\mathrm{R}]$ estimates describe |
| estimates esample:... | $[\mathrm{R}]$ estimates save |

Store and restore estimates in memory

| estimates store name | $[\mathrm{R}]$ estimates store |
| :--- | :--- |
| estimates restore name | $[\mathrm{R}]$ estimates store |
| estimates query | $[\mathrm{R}]$ estimates store |

| $\underline{\text { estimates for namelist: ... }}$ | $[R]$ estimates for |

## Remarks and examples

estimates is for use after you have fit a model, be it with regress, logistic, etc. You can use estimates after any estimation command, whether it be an official estimation command of Stata or a community-contributed one.
estimates has three separate but related capabilities:

1. You can save estimation results in a file on disk so that you can use them later, even in a different Stata session.
2. You can store up to 300 estimation results in memory so that they are at your fingertips.
3. You can make tables comparing any results you have stored in memory.

Remarks are presented under the following headings:

> Saving and using estimation results
> Storing and restoring estimation results
> Comparing estimation results
> Jargon

## Saving and using estimation results

After you have fit a model, say, with regress, type

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight displ foreign
    (output omitted)
```

You can save the results in a file:

```
. estimates save basemodel
file basemodel.ster saved
```

Later, say, in a different session, you can reload those results:

```
. estimates use basemodel
```

The situation is now nearly identical to what it was immediately after you fit the model. You can replay estimation results:

```
. regress
(output omitted)
```

You can perform tests:

```
. test foreign==0
(output omitted)
```

And you can use any postestimation command or postestimation capability of Stata. The only difference is that Stata no longer knows what the estimation sample, e (sample) in Stata jargon, was. When you reload the estimation results, you might not even have the original data in memory. That is okay. Stata will know to refuse to calculate anything that can be calculated only on the original estimation sample.

If it is important that you use a postestimation command that can be used only on the original estimation sample, there is a way you can do that. You use the original data and then use estimates esample: to tell Stata what the original sample was.

See $[R]$ estimates save for details.

## Storing and restoring estimation results

Storing and restoring estimation results in memory is much like saving them to disk. You type

```
. estimates store base
```

to save the current estimation results under the name base, and you type
. estimates restore base
to get them back later. You can find out what you have stored by typing

- estimates dir

Saving estimation results to disk is more permanent than storing them in memory, so why would you want merely to store them? The answer is that, once they are stored, you can use other estimates commands to produce tables and reports from them.

See [R] estimates store for details about the estimates store and restore commands.

## Comparing estimation results

Let's say that you have done the following:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight displ
    (output omitted)
- estimates store base
. regress mpg weight displ foreign
    (output omitted)
. estimates store alt
```

You can now get a table comparing the coefficients:
. estimates table base alt

| Variable | base | alt |
| ---: | :---: | ---: |
| weight | -.00656711 | -.00677449 |
| displacement | .00528078 | .00192865 |
| foreign |  | -1.6006312 |
| _cons | 40.084522 | 41.847949 |

estimates table can do much more; see [R] estimates table. etable also produces tables from stored estimates, customizes the tables, and exports to a variety of formats, including Word, PDF, ${ }^{L A} T_{E} X$, Excel, and HTML; see [R] etable. Also see [R] estimates stats. estimates stats works like estimates table but produces model comparisons in terms of BIC and AIC.

## Jargon

You know that if you fit a model, say, by typing
. regress mpg weight displacement
then you can later replay the results by typing
. regress
and you can do tests and calculate other postestimation statistics by typing

```
. test displacement==0
. estat vif
. predict mpghat
```

As a result, we often refer to the estimation results or the current estimation results or the most recent estimation results or the last estimation results or the estimation results in memory.

With estimates store and estimates restore, you can have many estimation results in memory. One set of those-the set most recently estimated or the set most recently restored-is the current or active estimation results, which you can replay, which you can test, or from which you can calculate postestimation statistics.

Current and active are the two words we will use interchangeably from now on.

## Also see

[P] _estimates - Manage estimation results

## Title

estimates describe - Describe estimation results

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Option | Remarks and examples | Stored results | Also see |

## Description

estimates describe describes the current (active) estimates. Reported are the command line that produced the estimates, any title that was set by estimates title (see [R] estimates title), and any notes that were added by estimates notes (see [R] estimates notes).
estimates describe name does the same but reports results for estimates stored by estimates store (see [R] estimates store).
estimates describe using filename does the same but reports results for estimates saved by estimates save (see [R] estimates save). If filename contains multiple sets of estimates (saved in it by estimates save, append), the number of sets of estimates is also reported. If filename is specified without an extension, .ster is assumed.

## Quick start

Describe current estimation results

```
estimates describe
```

Describe estimation results stored in m 1
estimates describe m1
Describe estimates from first model saved in mymodels.ster
estimates describe using mymodels
Same as above
estimates describe using mymodels, number(1)
Describe estimates from third model saved in mymodels.ster
estimates describe using mymodels, number(3)

## Menu

Statistics $>$ Postestimation

## Syntax

estimates describe
estimates describe name
estimates describe using filename [, number(\#)]
collect is allowed; see [U] 11.1.10 Prefix commands.

## Option

number (\#) specifies that the \#th set of estimation results from filename be described. This assumes that multiple sets of estimation results have been saved in filename by estimates save, append. The default is number (1).

## Remarks and examples

estimates describe can be used to describe the estimation results currently in memory,

```
. estimates describe
Estimation results produced by
. regress mpg weight displ if foreign
```

or to describe results saved by estimates save in a .ster file:

```
. estimates describe using final
Estimation results "Final results" saved on 12apr2022 14:20, produced by
    . logistic myopic age sex drug1 drug2 if complete==1
Notes:
    1. Used file patient.dta
    2. "datasignature myopic age sex drug1 drug2 if complete==1"
        reports 148:5(58763):2252897466:3722318443
    3. must be reviewed by rgg
```

## > Example 1

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight displ if foreign
(output omitted)
. estimates notes: file 'c(filename)'
. datasignature
    74:12(71728):3831085005:1395876116
. estimates notes: datasignature report 'r(datasignature)'
. estimates save foreign
file foreign.ster saved
. regress mpg weight displ if !foreign
    (output omitted)
```

```
estimates describe using foreign
Estimation results saved on 23mar2023 17:29, produced by
    . regress mpg weight displ if foreign
Notes:
    1. file https://www.stata-press.com/data/r18/auto.dta
    2. datasignature report 74:12(71728):3831085005:1395876116
```

## Stored results

estimates describe and estimates describe name store the following in $r()$ :
Macros
r(title) title
$r$ (cmdline) original command line
estimates describe using filename stores the above and the following in r() :
Scalars
$r$ (datetime) $\%$ tc value of date/time file saved
$r$ (nestresults) number of sets of estimation results in file

## Also see

[R] estimates - Save and manipulate estimation results

## Title

estimates for - Repeat postestimation command across models
Description Quick start Syntax Options Remarks and examples
Also see

## Description

estimates for performs postestimation_command on each estimation result specified.

## Quick start

Test for no effect of continuous covariate x 1 in stored estimates m 1 and m 2 estimates for m 1 m 2 : test $\mathrm{x} 1==0$

Same as above, but test interaction of binary covariate a and x 1
estimates for m1 m2: test 0.a\#c.x1==1.a\#c.x1
Linear combination of coefficients of x 1 and x 2 in all stored estimates
estimates for _all: lincom x1 + x2
Tables of margins for each level of a and confidence intervals using estimates m1 and m2
estimates for m1 m2: pwcompare i.a, cimargins

## Syntax

estimates for namelist [, options]: postestimation_command
where namelist is a name, a list of names,_all, or *. A name may be ., meaning the current (active) estimates. _all and $*$ mean the same thing.
options
Description
noheader
do not display title
nostop
do not stop if command fails

## Options

noheader suppresses the display of the header as postestimation_command is executed each time. nostop specifies that execution of postestimation_command is to be performed on the remaining models even if it fails on some.

## Remarks and examples

In the example that follows, we fit a model two different ways, store the results, and then use estimates for to perform the same test on both of them:

## $>$ Example 1

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. generate gpm = 1/mpg
. regress gpm i.foreign i.foreign#c.weight displ
    (output omitted)
. estimates store reg
. qreg gpm i.foreign i.foreign#c.weight displ
    (output omitted)
. estimates store qreg
. estimates for reg qreg: test 0.foreign#c.weight==1.foreign#c.weight
```

## Model reg

```
( 1) Ob.foreign#c.weight - 1.foreign#c.weight = 0
    F( 1, 69) = 4.87
        Prob > F = 0.0307
```

Model qreg
( 1) Ob.foreign\#c.weight - 1.foreign\#c.weight $=0$
$\mathrm{F}(1,69)=0.03$
Prob $>\mathrm{F}=0.8554$

## Also see

[R] estimates - Save and manipulate estimation results

## Title

estimates notes - Add notes to estimation results

Description Quick start Syntax Remarks and examples Also see

## Description

estimates notes: text adds a note to the current (active) estimation results. estimates notes and estimates notes list list the current notes.
estimates notes drop in noterange eliminates the specified notes.

## Quick start

Add "My note" to current estimation results estimates notes: My note

List all notes for current estimation results
estimates notes list
Same as above
estimates notes
Drop notes 1 to 3 from current estimation results
estimates notes drop in $1 / 3$
Drop last note applied to current estimation results
estimates notes drop in 1

## Syntax

```
estimates notes: text
estimates notes
estimates notes list [in noterange]
    estimates notes drop in noterange
```

where noterange is \# or \#/\# and where \# may be a number, the letter f (meaning first), or the letter $l$ (meaning last).

## Remarks and examples

After adding or removing notes, if estimates have been stored, do not forget to store them again. If estimates have been saved, do not forget to save them again.

Notes are most useful when you intend to save estimation results in a file; see $[R]$ estimates save. For instance, after fitting a model, you might type

```
. estimates note: I think these are final
```

. estimates save lock2
and later when going through your files, you could type

```
. estimates use lock2
. estimates notes
    1. I think these are final
```

Up to 9,999 notes can be attached to estimation results. If estimation results are important, we recommend that you add a note identifying the .dta dataset you used. The best way to do that is to type

```
. estimates notes: file 'c(filename)'
```

because 'c(filename)' will expand to include not just the name of the file but also its full path; see $[\mathrm{P}]$ creturn.

If estimation results took a long time to estimate-say, they were produced by cmmprobit or gllamm (see [CM] cmmprobit and http://www.gllamm.org) -it is also a good idea to add a data signature. A data signature takes less time to compute than reestimation when you need proof that you really have the right dataset. The easy way to do that is to type

```
. datasignature
    74:12(71728) : 3831085005:1395876116
. estimates notes: datasignature reports 'r(datasignature)'
```

Now when you ask to see the notes, you will see

```
estimates notes
```

1. I think these are final
2. file $C: \backslash p r o j e c t \backslash o n e \backslash p a t 4 . d t a$
3. datasignature reports 74:12(71728):3831085005:1395876116

## See [D] datasignature.

Notes need not be positive. You might set a note to be, "I need to check that age is defined correctly."
> Example 1

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight displ if foreign
(output omitted)
. estimates notes: file 'c(filename)'
. datasignature
    74:12(71728):3831085005:1395876116
. estimates notes: datasignature report 'r(datasignature)'
. estimates save foreign
file foreign.ster saved
```

```
estimates notes list in 1/2
    1. file https://www.stata-press.com/data/r18/auto.dta
    2. datasignature report 74:12(71728):3831085005:1395876116
    estimates notes drop in 2
    (1 note dropped)
    estimates notes
    1. file https://www.stata-press.com/data/r18/auto.dta
```

## Also see

[R] estimates - Save and manipulate estimation results

## Title

estimates replay - Redisplay estimation results
Description Quick start Menu Syntax Remarks and examples
Also see

## Description

estimates replay redisplays the current (active) estimation results, just as typing the name of the estimation command would do.
estimates replay namelist redisplays each specified estimation result. The active estimation results are left unchanged.

## Quick start

Redisplay current estimation results

```
estimates replay
```

Redisplay estimation results stored as m1
estimates replay m1
Redisplay all stored estimation results

```
estimates replay *
```

Same as above

```
estimates replay _all
```

## Menu

Statistics $>$ Postestimation

## Syntax

```
estimates replay
estimates replay namelist
```

where namelist is a name, a list of names, _all, or *. A name may be ., meaning the current (active) estimates. _all and $*$ mean the same thing.

## Remarks and examples

In the example that follows, we fit a model two different ways, store the results, use estimates for to perform the same test on both of them, and then replay the results:

## Example 1

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. generate gpm = 1/mpg
. regress gpm i.foreign i.foreign#c.weight displ
    (output omitted)
. estimates store reg
. qreg gpm i.foreign i.foreign#c.weight displ
    (output omitted)
. estimates store qreg
. estimates for reg qreg: test 0.foreign#c.weight==1.foreign#c.weight
```

## Model reg

```
( 1) Ob.foreign#c.weight - 1.foreign#c.weight = 0
    F( 1, 69) = 4.87
            Prob > F = 0.0307
```

Model qreg
( 1) Ob.foreign\#c.weight - 1.foreign\#c.weight $=0$
$\mathrm{F}(1,69)=0.03$
Prob > F = 0.8554
. estimates replay

Model qreg

. estimates replay reg

Model reg

[R] estimates - Save and manipulate estimation results

## Title

estimates save - Save and use estimation results

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Also see |

## Description

estimates save filename saves the current (active) estimation results in filename.
estimates use filename loads the results saved in filename into the current (active) estimation results.

In both cases, if filename is specified without an extension, .ster is assumed.
estimates esample: (note the colon) resets e(sample). After estimates use filename, $e$ (sample) is set to contain 0 , meaning that none of the observations currently in memory was used in obtaining the estimates.
estimates esample (without a colon) displays how e(sample) is currently set.

## Quick start

Save current estimation results to mymodels.ster estimates save mymodels

Add current estimation results to existing file mymodels.ster estimates save mymodels, append

Make active third estimation results saved in mymodels.ster estimates use mymodels, number (3)

Reset e(sample) to original estimation sample assuming command regress y x1 x2 estimates esample: y x1 x2

## Menu

Statistics $>$ Postestimation

## Syntax

```
estimates save filename [, append replace]
estimates use filename [, number(\#)]
estimates esample: [varlist] [if] [in] [weight]
    [, replace stringvars(varlist) zeroweight]
estimates esample
```

collect is allowed with estimates esample (without a colon); see [U] 11.1.10 Prefix commands.

## Options

append, used with estimates save, specifies that results be appended to an existing file. If the file does not already exist, a new file is created.
replace, used with estimates save, specifies that filename can be replaced if it already exists.
number(\#), used with estimates use, specifies that the \#th set of estimation results from filename be loaded. This assumes that multiple sets of estimation results have been saved in filename by estimates save, append. The default is number (1).
replace, used with estimates esample:, specifies that e(sample) can be replaced even if it is already set.
stringvars(varlist), used with estimates esample:, specifies string variables. Observations containing variables that contain "" will be omitted from e(sample).
zeroweight, used with estimates esample:, specifies that observations with zero weights are to be included in e(sample).

## Remarks and examples

See [R] estimates for an overview of the estimates commands.
For a description of estimates save and estimates use, see Saving and using estimation results in $[\mathrm{R}]$ estimates.

The rest of this entry concerns e(sample).
Remarks are presented under the following headings:

```
Setting e(sample)
Resetting e(sample)
Determining who set e(sample)
```

## Setting e(sample)

After estimates use filename, the situation is nearly identical to what it was immediately after you fit the model. The one difference is that e (sample) is set to 0 .
$e$ (sample) is Stata's function to mark which observations among those currently in memory were used in producing the estimates. For instance, you might type

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight displ if foreign
(output omitted)
. summarize mpg if e(sample)
(output omitted)
```

and summarize would report the summary statistics for the observations regress in fact used, which would exclude not only observations for which foreign $=0$ but also any observations for which mpg, weight, or displ was missing.

If you saved the above estimation results and then reloaded them, however, summarize mpg if e(sample) would produce

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | :---: | :---: | :---: | :---: | :---: |
| $m p g$ | 0 |  |  |  |  |

Stata thinks that none of these observations was used in producing the estimates currently loaded.
What else could Stata think? When you estimates use filename, you do not have to have the original data in memory. Even if you do have data in memory that look like the original data, they might not be. Setting e (sample) to 0 is the safe thing to do. There are some postestimation statistics, for instance, that are appropriate only when calculated on the estimation sample. Setting e (sample) to 0 ensures that if you ask for one of them, you will get back a null result.

We recommend that you leave e(sample) set to 0 . But what if you really need to calculate that postestimation statistic? Well, you can get it, but you are going to be responsible for setting e(sample) correctly. Here we just happen to know that all the observations with foreign $=1$ were used, so we can type

```
. estimates esample: if foreign
```

If all the observations had been used, we could simply type

```
. estimates esample:
```

The safe thing to do, however, is to look at the estimation command-estimates describe will show it to you-and then type

```
. estimates esample: mpg weight displ if foreign
```

We include all observations with foreign $=1$, excluding any with missing values in the mpg , weight, or displ variable, that are to be treated as the estimation sample.

## Resetting e(sample)

estimates esample: will allow you to not only set but also reset e(sample). If e(sample) has already been set (say that you just fit the model) and you try to set it, you will see

```
. estimates esample: mpg weight displ if foreign
no; e(sample) already set
r(322);
```

Here you can specify the replace option:

```
. estimates esample: mpg weight displ if foreign, replace
```

We do not recommend resetting e (sample), but the situation can arise where you need to. Imagine that you estimates use filename, you set e(sample), and then you realize that you set it wrong. Here you would want to reset it.

## Determining who set e(sample)

estimates esample without a colon will report whether and how e(sample) was set. You might see

```
. estimates esample
```

$e$ (sample) set by estimation command
or

```
. estimates esample
e(sample) set by user
```

or
estimates esample
e(sample) not set (0 assumed)

## Stored results

estimates esample without the colon saves macro $r$ (who), which will contain cmd, user, or zero'd.

## Also see

[R] estimates - Save and manipulate estimation results

## Title

estimates selected - Show selected coefficients

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Also see |

## Description

estimates selected reports on coefficients from one or more estimation results. It creates a table that indicates which coefficients were estimated in each model and, if requested, reports the value of those coefficients. The results may be sorted based on the values of the estimated coefficients or based on variable names.

## Quick start

Compare coefficients for stored estimates m 1 and m 2

```
estimates selected m1 m2
```

Same as above, but display a $u$ for covariates that are not specified in the model

```
estimates selected m1 m2, display(u)
```

Compare stored estimates 11 and 12, and order the rows by absolute values of the coefficients estimates selected 11 12, sort(coef)

## Menu

Statistics $>$ Postestimation

## Syntax

estimates selected [namelist] [, options]
namelist is the name given to previously stored estimation results, a list of names, _all, or *. A name may be ., meaning the current (active) estimates. _all and $*$ mean the same thing.
options
Description
Main
display(info) display info; default is display(x)
sort(on)
Reporting
noabbrev
display_options
sort rows in order of on
do not abbreviate variable names
control row spacing, line width, and display of omitted variables and base and empty cells

[^22]
## Options

$\qquad$
display (info) specifies what to display in the table. The default is display(x).
Blank cells in the table indicate that the corresponding covariate does not have a fitted value. For some covariates without fitted values, a code that indicates the reason for omission is reported in the table. Base levels of factors and interactions are coded with the letter b. Empty levels of factors and interactions are coded with the letter e. Covariates omitted because of collinearity are coded with the letter o.
display ( $x$ ) displays an $x$ in the cell of the table where a covariate has a fitted value. This is the default.
display (u) is the same as display ( x ), except that when a covariate was not specified in the model, $u$ (for unavailable) is displayed instead of a blank cell.
display (coef [, eform format $(\% f m t)]$ ) specifies that coefficient values be displayed in the table.
eform displays coefficients in exponentiated form. For each coefficient, $e^{b}$ rather than $b$ is displayed. This option can be used to display odds ratios, incidence-rate ratios, relative-risk ratios, hazard ratios, and subhazard ratios after the appropriate estimation command.
format ( $\%$ frit ) specifies the display format for the coefficients in the table. The default is format (\%9.0g).
sort (on) specifies how to sort the rows of the table. By default, coefficients are displayed in the order in which they appear in the estimation results.
sort (none) specifies that the rows are not sorted. This is the default. The order of the coefficients is taken from their order in $e(b)$.
sort (names) orders rows alphabetically by the variable names of the covariates. In the case of factor variables, main effects and nonfactor variables are displayed first in alphabetical order; then all two-way interactions are displayed in alphabetical order, then all three-way interactions, and so on.
sort (coef) orders rows in descending order by the absolute values of the coefficients. When results from two or more estimation results are displayed, results are sorted first by the ordering for the first estimation result with rows representing coefficients not in the first estimation result last. Within the rows representing coefficients not in the first estimation result, the rows are sorted by the ordering for the second estimation result with rows representing coefficients not in the first or second estimation results last. And so on.

Reporting
noabbrev prevents variable names from being abbreviated in the row titles of the table. Long variable names are split onto multiple lines if they do not fit.
display_options: vsquish, fvwrap(\#), fvwrapon(style), and nolstretch; see [R] Estimation options.

## Remarks and examples

estimates selected produces a table based on estimated coefficients from one or more models. Results can be sorted by the values of the estimated coefficients or by variable names. Multiple
models are displayed side-by-side, making it easy to compare which covariates were included in each model or to compare the estimated values of those coefficients.
> Example 1: Compare coefficients across models
To compare coefficients from two or more models, we first need to store the results of each model using estimates store; see [R] estimates store. Then we use estimates selected to obtain a table comparing which coefficients were estimated in each model. By default, the table reports an x for each coefficient that was estimated.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg gear turn
    (output omitted)
. estimates store small
. regress mpg gear turn length
(output omitted)
. estimates store large
. estimates selected small large
```

|  | small | large |
| ---: | :---: | :---: |
| gear_ratio | x | x |
| turn | x | x |
| length |  | x |
| _cons | x | x |

Legend:
b - base level
e - empty cell
o - omitted
x - estimated

There is only one difference in the two regress commands; the large model includes length as a covariate, but the small model does not. Therefore, the above table displays x's for all but the length coefficient in the small model. When working with larger models or with more models, this type of table makes it easy to spot the differences in the model specification.

By default, the rows of the table in the order that covariates appear in the models. To sort the results on the covariate names, we add the sort (names) option.

```
. estimates selected small large, sort(names)
```

|  | small | large |
| ---: | :---: | :---: |
| gear_ratio | x | x |
| length |  | x |
| turn | x | x |
| _cons | x | x |

```
Legend:
    b - base level
    e - empty cell
    o - omitted
    x - estimated
```

We could have instead sorted on the values of the estimated coefficients by including the sort (coef) option.

To display the coefficients values instead of the x's, we add the display(coef) option.
. estimates selected small large, sort(names) display(coef)

|  | small | large |
| ---: | ---: | ---: |
| gear_ratio | 3.032884 | 1.35666 |
| length |  | -.1665899 |
| turn | -.7330502 | -.1219185 |
| _cons | 41.21801 | 53.3487 |

Legend:
b - base level
e - empty cell
o - omitted

## Stored results

estimates selected stores the following in $r()$ :
Macros
$r$ (names) names of results used
Matrices
r(coef) matrix $M: n \times m$
$M[i, j]=i$ th coefficient estimate for model $j ; i=1, \ldots, n ; j=1, \ldots, m$

## Also see

## Title

estimates stats - Model-selection statistics

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| Also see |  |  |  |

## Description

estimates stats reports model-selection statistics, including the Akaike (AIC), consistent Akaike's (CAIC), corrected Akaike's (AICc), and Schwarz's Bayesian (BIC) information criteria. These measures are appropriate for maximum likelihood models.

If estimates stats is used for a non-likelihood-based model, such as qreg, missing values are reported.

## Quick start

Display AIC and BIC for last estimation command estimates stats

Display AIC and BIC for stored estimates m1 and m2
estimates stats m1 m2
Same as above, but display CAIC instead of AIC
estimates stats m1 m2, aicconsistent
Same as above, but display AICc instead of AIC
estimates stats m 1 m 2 , aiccorrected
Same as above, but display all AIC, BIC, AICc, and CAIC
estimates stats m 1 m 2 , all
Specify $N=1,000$ for calculation of BIC
estimates stats, $\mathrm{n}(1000)$
Same as above, but use 10 degrees of freedom
estimates stats, $\mathrm{n}(1000) \mathrm{df}(10)$

## Menu

Statistics $>$ Postestimation

## Syntax

estimates stats [namelist] [, options]
where namelist is a name, a list of names,__all, or *. A name may be ., meaning the current (active) estimates. _all and $*$ mean the same thing.
options

| aiccorrected | report AICc instead of AIC <br> report CAIC instead of AIC |
| :--- | :--- |
| aicconsistent | report all four information criteria: AIC, BIC, AICc, and CAIC <br> all <br> $\mathrm{n}(\#)$ |
| $\mathrm{df}(\#)$ | specify $N$ to be used in calculating BIC, AICc, and CAIC; <br> secify degrees of freedom $k$ to be used in calculating AIC, BIC, <br> AICc, and CAIC |
| icdetail | produce a table showing the type of $N$ used in BIC, AICc, and <br>  <br> CAIC calculation |

collect is allowed; see [U] 11.1.10 Prefix commands.

## Options

aiccorrected specifies that AICc be computed instead of AIC. This information criterion is a second-order approximation and is recommended for small sample sizes.

Only one of aiccorrected, aicconsistent, or all is allowed.
aicconsistent specifies that CAIC be computed instead of AIC. This information criterion is a consistent version of AIC; that is, the probability of selecting the "true model" approaches 1 as sample size increases.
Only one of aicconsistent, aiccorrected, or all is allowed.
all produces a table showing all four information criteria: AIC, BIC, AICc, and CAIC.
Only one of all, aiccorrected, or aicconsistent is allowed.
$\mathrm{n}(\#)$ specifies $N$ to be used in calculating BIC, AICc, and CAIC; see [R] IC note.
$\mathrm{df}(\#)$ specifies degrees of freedom $k$ to be used in calculating AIC, BIC, AICc, and CAIC. By default, $k$ is the number of estimated parameters.
icdetail produces a table showing the type of $N$ used in BIC, AICc, and CAIC calculations. Most estimation commands use the number of observations in the estimation sample for the information criteria. For some models, however, other types of $N$, such as the number of cases in choice models, should be used. When the default table of estimates stats contains more than one type of $N$, specifying icdetail allows you to see the different types of $N$ used for BIC, AICc, and CAIC.

## Remarks and examples

If you type estimates stats without arguments, a table for the most recent estimation results will be shown:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. logistic foreign mpg weight displ
    (output omitted)
. estimates stats
Akaike's information criterion and Bayesian information criterion
```

| Model | N | ll (null) | ll(model) | df | AIC | BIC |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| . | 74 | -45.03321 | -20.59083 | 4 | 49.18167 | 58.39793 |

Note: BIC uses $N=$ number of observations. See [R] IC note.
Regarding the note at the bottom of the table, $N$ is an ingredient in the calculation of BIC, AICc, and CAIC; see $[R]$ IC note. The note changes if you specify the $n()$ option, which tells estimates stats what $N$ to use. By default, $N$ is the number of observations used in fitting the model.

Regarding the table itself, 11 (null) is the log likelihood for the constant-only model, 11 (model) is the $\log$ likelihood for the model, df is the number of degrees of freedom, and AIC and BIC are the Akaike and Bayesian information criteria, respectively.

Models with smaller values of an information criterion are considered preferable.
estimates stats can compare estimation results:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. logistic foreign mpg weight displ
(output omitted)
. estimates store full
. logistic foreign mpg weight
(output omitted)
. estimates store sub
. estimates stats full sub
Akaike's information criterion and Bayesian information criterion
```

| Model | N | ll(null) | ll(model) | df | AIC | BIC |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| full | 74 | -45.03321 | -20.59083 | 4 | 49.18167 | 58.39793 |
| sub | 74 | -45.03321 | -27.17516 | 3 | 60.35031 | 67.26251 |

Note: BIC uses $N=$ number of observations. See [R] IC note.

You can use option all to compare the models based on all four information criteria
. estimates stats full sub, all
Information criteria

| Model | N | ll(null) | ll(model) | df |
| ---: | ---: | ---: | ---: | ---: |
| full | 74 | -45.03321 | -20.59083 | 4 |
| sub | 74 | -45.03321 | -27.17516 | 3 |

Note: BIC, AICc, and CAIC use $\mathrm{N}=$ number of observations. See [R] IC note.

| Model | AIC | BIC | AICc | CAIC |
| ---: | ---: | ---: | ---: | ---: |
| full | 49.18167 | 58.39793 | 49.76138 | 62.39793 |
| sub | 60.35031 | 67.26251 | 60.69317 | 70.26251 |

Legend: AIC is Akaike's information criterion.
BIC is Bayesian information criterion.
AICc is corrected Akaike's information criterion.
CAIC is consistent Akaike's information criterion.
All four information criteria suggest that the full model is preferable.

## Stored results

estimates stats stores the following in r() :
Matrices
$r(S) \quad$ matrix with columns (N, ll(null), 11 (model), df, and information criteria) and rows corresponding to models in the table

## Methods and formulas

See [R] IC note.

## Also see

[R] estimates - Save and manipulate estimation results

## Title

estimates store - Store and restore estimation results

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Option | Remarks and examples | Stored results | References |
| Also see |  |  |  |

## Description

estimates store name stores the current (active) estimation results under the name name.
estimates restore name loads the results stored under name into the current (active) estimation results.
estimates query tells you whether the current (active) estimates have been stored and, if so, the name.
estimates dir displays a list of the stored estimates.
estimates drop namelist drops the specified stored estimation results.
estimates clear drops all stored estimation results.
estimates clear, estimates drop _all, and estimates drop $*$ do the same thing. estimates drop and estimates clear do not eliminate the current (active) estimation results.

## Quick start

Store estimation results as m 1 for use later in the same session estimates store m1

Restore estimation results from m 2
estimates restore m2
Find out whether the current estimation results have been stored
estimates query
Display table of information about all stored results
estimates dir
Drop stored estimation results m3
estimates drop m3
Drop all stored results
estimates clear

## Menu

Statistics $>$ Postestimation

## Syntax

```
estimates store name [, nocopy]
    estimates restore name
    estimates query
    estimates dir [namelist]
    estimates drop namelist
    estimates clear
```

where namelist is a name, a list of names, _all, or *. _all and * mean the same thing.
collect is allowed with estimates dir; see [U] 11.1.10 Prefix commands.

## Option

nocopy, used with estimates store, specifies that the current (active) estimation results are to be moved into name rather than copied. Typing

- estimates store hold, nocopy
is the same as typing
. estimates store hold
. ereturn clear
except that the former is faster. The nocopy option is sometimes used by programmers.

## Remarks and examples

estimates store stores estimation results in memory so that you can access them later.
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight displ (output omitted)
. estimates store myreg
. . . . you do other things, including fitting other models . . .

- estimates restore myreg
. regress
(same output shown again)
After estimates restore myreg, things are once again just as they were, estimationwise, just after you typed regress mpg weight displ.
estimates store stores results in memory. When you exit Stata, those stored results vanish. If you wish to make a permanent copy of your estimation results, see [R] estimates save.

The purpose of making copies in memory is 1) so that you can quickly switch between them and 2) so that you can make tables comparing estimation results. Concerning the latter, see [R] estimates table, $[R]$ etable, and $[R]$ estimates stats.

## Stored results

estimates dir stores the following in r() :
Macros
$r$ (names) names of stored results

collect is allowed; see [U] 11.1.10 Prefix commands.
title() does not appear in the dialog box.

## Options

## Main

stats (scalarlist) specifies a list of any of or all the names of scalars stored in e() to be displayed in the table. scalarlist may also contain the following:

| aic | Akaike's information criterion |
| :--- | :--- |
| bic | Schwarz's Bayesian information criterion |
| rank | rank of $e(V)$ (\# of free parameters in model) |

The specified statistics do not have to be available for all estimation results being displayed.
For example, stats (N ll chi2 aic) specifies that e(N), e(ll), e(chi2), and AIC be included. In Stata, e(N) records the number of observations; e(ll), the log likelihood; and e(chi2), the $\chi^{2}$ test that all coefficients in the first equation of the model are equal to zero.
star and star (\#1 \#2 \#3) specify that stars (asterisks) are to be used to mark significance. The second syntax specifies the significance for one, two, and three stars. If you specify simply star, that is equivalent to specifying star(.05 .01 .001), which means one star $\left(^{*}\right.$ ) if $p<0.05$, two stars $(* *)$ if $p<0.01$, and three stars $(* * *)$ if $p<0.001$.
The star and star() options may not be combined with the se, $t$, or p option.

## Options

keep (coeflist) and drop (coeflist) are alternatives; they specify coefficients to be included or omitted from the table. The default is to display all coefficients.
If keep () is specified, it specifies not only the coefficients to be included but also the order in which they appear.

A coeflist is a list of coefficient names, each name of which may be simple (for example, price), an equation name followed by a colon (for example, mean:), or a full name (for example, mean:price). Names are separated from each other by blanks.
When full names are not specified, all coefficients that match the partial specification are included. For instance, drop (_cons) would omit _cons for all equations.
equations (matchlist) specifies how the equations of the models in namelist are to be matched. The default is to match equations by name. Matching by name usually works well when all results were fit by the same estimation command. When you are comparing results from different estimation commands, however, specifying equations() may be necessary.
The most common usage is equations(1), which indicates that all first equations are to be matched into one equation named \#1.
matchlist has the syntax

$$
\operatorname{term}[, \operatorname{term} \ldots]
$$

term is

$$
\begin{array}{ll}
{[\text { eqname }=] \#: \# \ldots: \#} & (\text { syntax } 1) \\
{[\text { eqname }=] \#} & (\text { syntax } 2)
\end{array}
$$

In syntax 1, each \# is a number or a period (.). If a number, it specifies the position of the equation in the corresponding model; 1:3:1 would indicate that equation 1 in the first model matches equation 3 in the second, which matches equation 1 in the third. A period indicates that there
is no corresponding equation in the model; 1:.:1 indicates that equation 1 in the first matches equation 1 in the third.
In syntax 2 , you specify just one number, say, 1 or 2 , and that is shorthand for $1: 1 \ldots: 1$ or $2: 2 \ldots: 2$, meaning that equation 1 matches across all models specified or that equation 2 matches across all models specified.

Now that you can specify a term, you can put that together into a matchlist by separating one term from the other by commas. In what follows, we will assume that three names were specified,

```
. estimates table alpha beta gamma, ...
```

equations(1) is equivalent to equations(1:1:1); we would be saying that the first equations match across the board.
equations ( $1: .: 1$ ) would specify that equation 1 matches in models alpha and gamma but that there is nothing corresponding in model beta.
equations $(1,2)$ is equivalent to equations $(1: 1: 1,2: 2: 2)$. We would be saying that the first equations match across the board and so do the second equations.
equations ( $1,2: .: 2$ ) would specify that the first equations match across the board, that the second equations match for models alpha and gamma, and that there is nothing equivalent to equation 2 in model beta.

If equations() is specified, equations not matched by position are matched by name.
$\mathrm{b}(\% \mathrm{fmt})$ specifies how the coefficients are to be displayed. You might specify $\mathrm{b}(\% 9.2 \mathrm{f})$ to make decimal points line up. There is also a b option, which specifies that coefficients are to be displayed, but that is just included for consistency with the $s e$, $t$, and $p$ options. Coefficients are always displayed.
se, t , and p specify that standard errors, $t$ or $z$ statistics, and $p$-values are to be displayed. The default is not to display them. se (\%fmt), $\mathrm{t}(\% f m t)$, and $\mathrm{p}(\% f m t)$ specify that each is to be displayed and specifies the display format to be used to format them.
stfmt (\% fint) specifies the format for displaying the scalar statistics included by the stats() option.

General format
varwidth (\#) specifies the number of character positions used to display the names of the variables and statistics. The default is 12 .
modelwidth(\#) specifies the number of character positions used to display the names of the models. The default is 12 .
eform displays coefficients in exponentiated form. For each coefficient, $\exp (\boldsymbol{\beta})$ rather than $\boldsymbol{\beta}$ is displayed, and standard errors are transformed appropriately. Display of the intercept, if any, is suppressed.
varlabel specifies that variable labels be displayed instead of variable names.
newpanel specifies that the statistics be displayed in a table separated by a blank line from the table with coefficients rather than in the style of another equation in the table of coefficients.
style(stylespec) specifies the style of the coefficient table.
style(oneline) specifies that a vertical line be displayed after the variables but not between the models. This is the default.
style(columns) specifies that vertical lines be displayed after each column. style(noline) specifies that no vertical lines be displayed.
coded specifies that a compact table be displayed. This format is especially useful for comparing variables that are included in a large collection of models.
$\qquad$ Reporting
display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), and fvwrapon(style); see [R] Estimation options.

The following option is available with estimates table but is not shown in the dialog box: title (string) specifies the title to appear above the table.

## Remarks and examples

estimates table lets you format estimation results and organize results from multiple models in a single table. You achieve this by combining estimates table with estimates store; see $[R]$ estimates store. When combined with putdocx or putpdf, estimates table lets you create customized tables of results in . docx or .pdf format.

Alternatively, you can use etable to create a table with the results stored with estimates store. The advantage of using etable is that you can add notes to your table and export it to a variety of file types, such as HTML and LATEX.

## > Example 1: Creating the default table

If you type estimates table without arguments, a table of the most recent estimation results will be shown:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight
    (output omitted)
. regress mpg weight displ
(output omitted)
. estimates table
\begin{tabular}{r|r}
\hline Variable & Active \\
\hline weight & -.00656711 \\
displacement & .00528078 \\
_cons & 40.084522 \\
\hline
\end{tabular}
```

In the above output table, only the results from the second regress command are displayed because they are the current (active) estimates.

By default, estimates table displays only coefficient estimates. You can request additional model statistics by specifying the stats() option. Estimation commands store e-class results. To see a list of available results from the last estimation command that can be specified in the stats() option, you can use the ereturn list command.

## > Example 2: Creating a table with multiple models

If we want to display more than one set of estimation results in a single table, we can use estimates store to store each set of estimation results in memory so that they can be accessed later by estimates table. This is one of the primary uses of estimates table-comparing estimation results:

```
. regress mpg weight displ
(output omitted)
. estimates store base
. regress mpg weight displ i.foreign
(output omitted)
. estimates store alt
. qreg mpg weight displ i.foreign
(output omitted)
. estimates store qreg
. estimates table base alt qreg, stats(r2)
```

| Variable | base | alt | qreg |
| ---: | :---: | ---: | ---: |
| weight <br> foreign <br> Foreign | -.00656711 | -.00677449 | -.00595056 |
| .00528078 | .00192865 | .00018552 |  |
| _cons | 40.084522 | 41.847949 | 39.213348 |
| $r 2$ | .6529307 | .66287957 |  |

estimates table automatically lines up the point estimates of coefficients on covariates that are common across each model. The stats (r2) option specifies that the coefficient of determination ( $R^{2}$ ) be placed under the models for which it is computed.

The foreign variable was included in the models alt and qreg as a factor variable. Because the values of foreign are labeled, the value labels are displayed by default. See [D] label for information about managing value labels.

## > Example 3: Creating and exporting a formatted table

We can add estimates of the standard errors to the table and format them along with the original coefficient estimates by using the b() and se() options.

As shown in example 2, the labeled values of any factor variables are displayed by default. To see the labels corresponding to the variables that are included in the model rather than the names of the variables, we can specify the varlabel option.

```
. estimates table alt, b(%5.4f) se(%5.4f) varlabel
```

| Variable | alt |
| ---: | ---: |
| Weight (lbs.) | -0.0068 |
|  | 0.0012 |
| Displacement (cu. in.) | 0.0019 |
|  | 0.0101 |
| Car origin |  |
| Foreign | -1.6006 |
|  | 1.1136 |
| Constant | 41.8479 |
|  | 2.3507 |

Legend: b/se
If we wanted this table to appear in a Word document, we could use the putdocx command with the etable output type to write it to a new document. To create the new document myresults.docx, we would type the following putdocx commands:

```
. putdocx begin
. putdocx table results = etable
. putdocx save myresults.docx
successfully created "myresults.docx"
```

This creates a table in Word that looks like

## Stored results

estimates table stores the following in $r()$ :
Macros
$r$ (names) names of results used
Matrices

$$
\begin{array}{ll}
\text { r(coef) } & \text { matrix } M: n \times 2 * m \\
& M[i, 2 j-1]=i \text { th parameter estimate for model } j ; \\
& M[i, 2 j]=\text { variance of } M[i, 2 j-1] ; i=1, \ldots, n ; j=1, \ldots, m \\
\text { r(stats) } \quad \text { matrix } S: k \times m \text { (if option stats() specified) } \\
& S[i, j]=i \text { th statistic for model } j ; i=1, \ldots, k ; j=1, \ldots, m
\end{array}
$$

## Title

estimates title - Set title for estimation results

Description Quick start Menu Syntax Remarks and examples Also see

## Description

estimates title: (note the colon) sets or clears the title for the current estimation results. The title is used by estimates table, estimates stats, and estimates dir.
estimates title without the colon displays the current title.

## Quick start

Set title for the current estimation results

```
estimates title: Base model
```

Display the title of the current estimation results

```
estimates title
```

## Menu

Statistics $>$ Postestimation

## Syntax

```
estimates title: [text]
estimates title
```

## Remarks and examples

After setting the title, if estimates have been stored, do not forget to store them again:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg gear turn
    (output omitted)
. estimates store reg
```

Now let's add a title:

```
. estimates title: "My regression"
```

## Title

Estimation options - Estimation options

Description Syntax Options Also see

## Description

This entry describes the options common to many estimation commands. Not all the options documented here work with all estimation commands. See the documentation for the particular estimation command; if an option is listed there, it is applicable.

## Syntax

Model

```
noconstant
offset(varname o)
exposure(\mp@subsup{varname e}{e}{})
constraints(constraints)
```

Reporting
level(\#)
lrmodel
nocnsreport
noci
nopvalues
noomitted
vsquish
noemptycells
baselevels
allbaselevels
nofvlabel
fvwrap(\#)
fvwrapon(style)
cformat (\% fmt)
pformat (\%fmt)
sformat (\%fmt)
Integration
intmethod(intmethod)
intpoints(\#)
nolstretch
collinear
coeflegend
suppress constant term
include varname $_{o}$ in model with coefficient constrained to 1 include $\ln \left(\right.$ varname $\left._{e}\right)$ in model with coefficient constrained to 1 apply specified linear constraints
set confidence level; default is level (95)
perform likelihood-ratio model test instead of the default Wald test do not display constraints
suppress confidence intervals
suppress $p$-values and their test statistics
do not display omitted collinear variables
suppress blank space separating factor variables or time-series variables
do not display empty interaction cells of factor variables
report base levels for factor variables and interactions
display all base levels for factor variables and interactions
display factor-variable level values rather than value labels
allow \# lines when wrapping long value labels
apply style for wrapping long value labels;
style may be word or width
format for coefficients, standard errors, and confidence limits
format for $p$-values
format for test statistics
integration method for random-effects models
use \# integration (quadrature) points
do not automatically widen coefficient table for long variable names keep collinear variables
display legend instead of statistics

## Options

## Model

noconstant suppresses the constant term (intercept) in the model.
offset $\left(\right.$ varname $\left._{o}\right)$ specifies that varname ${ }_{o}$ be included in the model with the coefficient constrained to be 1 .
exposure ( varname $_{e}$ ) specifies a variable that reflects the amount of exposure over which the depvar events were observed for each observation; $\ln \left(\right.$ varname $\left._{e}\right)$ with the coefficient constrained to be 1 is entered into the log-link function.
constraints (numlist $\mid$ matname) specifies the linear constraints to be applied during estimation. The default is to perform unconstrained estimation. See $[R]$ reg3 for the use of constraints in multiple-equation contexts.
constraints (numlist) specifies the constraints by number after they have been defined by using the constraint command; see [R] constraint. Some commands (for example, slogit) allow only constraints (numlist).
constraints (matname) specifies a matrix containing the constraints; see $[\mathrm{P}]$ makecns.

## Reporting

level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.
lrmodel specifies to conduct a likelihood-ratio test of the full maximum-likelihood model versus the restricted model that includes only a constant term in the regression equation instead of conducting the default Wald test that all coefficients are zero. This option can substantially increase estimation time.
lrmodel may not be specified with the vce(robust), vce(cluster clustvar), vce(jackknife), vce(bootstrap), or noconstant option.
lrmodel may not be combined with constraints; see constraints (constraints). In some cases, a likelihood-ratio test is valid for models with constraints. To compute a likelihood-ratio test when constraints have been applied during estimation, use lrtest; see [R] lrtest.
lrmodel may not be specified with the jackknife, bootstrap, svy, or mi estimate prefix. In addition, lrmodel may not be specified on replay.
nocnsreport specifies that no constraints be reported. The default is to display user-specified constraints above the coefficient table.
noci suppresses confidence intervals from being reported in the coefficient table.
nopvalues suppresses $p$-values and their test statistics from being reported in the coefficient table.
noomitted specifies that variables that were omitted because of collinearity not be displayed. The default is to include in the table any variables omitted because of collinearity and to label them as "(omitted)".
vsquish specifies that the blank space separating factor-variable terms or time-series-operated variables from other variables in the model be suppressed.
noemptycells specifies that empty cells for interactions of factor variables not be displayed. The default is to include in the table interaction cells that do not occur in the estimation sample and to label them as "(empty)".
baselevels and allbaselevels control whether the base levels of factor variables and interactions are displayed. The default is to exclude from the table all base categories.
baselevels specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables.
allbaselevels specifies that all base levels of factor variables and interactions be reported.
nofvlabel displays factor-variable level values rather than attached value labels. This option overrides the fvlabel setting; see $[R]$ set showbaselevels.
fvwrap(\#) specifies how many lines to allow when long value labels must be wrapped. Labels requiring more than \# lines are truncated. This option overrides the fvwrap setting; see [R] set showbaselevels.
fvwrapon(style) specifies whether value labels that wrap will break at word boundaries or break based on available space.
fvwrapon(word), the default, specifies that value labels break at word boundaries.
fvwrapon(width) specifies that value labels break based on available space.
This option overrides the fvwrapon setting; see [R] set showbaselevels.
cformat (\% fmt) specifies how to format coefficients, standard errors, and confidence limits in the coefficient table. The maximum format width is 9 . See [R] set cformat.
pformat (\%fint) specifies how to format $p$-values in the coefficient table. The maximum format width is 5 . See [R] set cformat.
sformat (\% $\% m t$ ) specifies how to format test statistics in the coefficient table. The maximum format width is 8 . See $[R]$ set cformat.
$\qquad$ Integration
intmethod(intmethod) specifies the integration method to be used for the random-effects model. It accepts one of four arguments: mvaghermite, the default for all but a crossed random-effects model, performs mean and variance adaptive Gauss-Hermite quadrature; mcaghermite performs mode and curvature adaptive Gauss-Hermite quadrature; ghermite performs nonadaptive GaussHermite quadrature; and laplace, the default for crossed random-effects models, performs the Laplacian approximation.
intpoints(\#) specifies the number of integration points to use for integration by quadrature. The default is intpoints (12); the maximum is intpoints(195). Increasing this value improves the accuracy but also increases computation time. Computation time is roughly proportional to its value.

The following options are not shown in the dialog box:
nolstretch specifies that the width of the coefficient table not be automatically widened to accommodate longer variable names. The default, lstretch, is to automatically widen the coefficient table up to the width of the Results window. Specifying lstretch or nolstretch overrides the setting given by set lstretch. If set lstretch has not been set, the default is lstretch.
collinear specifies that the estimation command not omit collinear variables. This option is seldom used because collinear variables make a model unidentified. However, you can add constraints to a model that will identify it even with collinear variables. For example, if variables x1 and x2 are collinear, but you constrain the coefficient on x 2 to be a multiple of the coefficient on x 1 , then your model is identified even with collinear variables. In such cases, you specify collinear so that both x 1 and x 2 are retained in the model.
coeflegend specifies that the legend of the coefficients and how to specify them in an expression be displayed rather than displaying the statistics for the coefficients.

## Title

etable - Create a table of estimation results

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Appendix | Acknowledgments |
| Reference | Also see |  |  |

## Description

The etable command allows you to easily create a table of estimation results and export it to a variety of file types. You can create a table complete with a title, notes, stars for indicating significant results, and more.

## Quick start

Create a table from the active estimation results, reporting the coefficients, standard errors, and number of observations
etable
Same as above, and display stars for significant results and a note indicating what the stars represent etable, showstars showstarsnote

Create a table with title "My title" and note "My note"
etable, title("My title") note("My note")
Create a table with stored estimates model1 and model2, along with the number of observations and adjusted $R^{2}$ value for each model
etable, estimates(model1 model2) mstat(N) mstat(r2_a)
Same as above, and export the table to myfile.tex
etable, estimates(model1 model2) mstat(N) mstat(r2_a) export(myfile.tex)

## Menu

| tableonly |  |

smcl_option Description
append $\quad$ append to an existing file
txt_option
Description
append append to an existing file
md_option
Description
append
append to an existing file
fontfamily specifies a valid font family.
unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.
variant may be allcaps, smallcaps, or normal.
variant (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, LATEX, and HTML files.
variant (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, LATEX, and HTML files.
variant (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, $\mathrm{LA}_{\mathrm{E}} \mathrm{X}$, and HTML files.
upattern may be any of the patterns listed in the Appendix. For example, underline (none) removes the underline from the statistic, and underline (single) underlines the statistic. All other upatterns are available only when publishing items from a collection to Microsoft Word.
smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.
latex specifies the name of a $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ macro to render text for $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ output. Example $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ macro names are textbf, textsf, textrm, and texttt. Custom LATEX macros are also allowed. If text is to be rendered in a cell, title, or note, then latex is translated to the following when you export to $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ :

## $\backslash$ latex $\{$ text $\}$

sspec is
[background(bgcolor) foreground(fgcolor) pattern(fpattern)]
bgcolor specifies the background color.
fgcolor specifies the foreground color.
fpattern specifies the fill pattern. A complete list of fill patterns is shown in the Appendix.
bgcolor, fgcolor, and color may be one of the colors listed in the Appendix; a valid RGB value in the form \#\#\# \#\#\# \#\#\#, for example, 171248 103; or a valid RRGGBB hex value in the form \#\#\#\#\#\#, for example, ABF867.
sfmt is the specification for a string format in option sformat () and may contain a mix of text and $\% s$. Here $\%$ s refers to the statistic value that is formatted as specified using nformat(). The text will be placed around the statistic as it is placed around $\% \mathrm{~s}$ in this option. For instance, to place parentheses around the statistic, you can specify sformat (" (\%s)").
Two text characters must be specified using a special character sequence if you want them to be displayed in your collection. To include $\%$, type $\% \%$. To include $\backslash$, type $\backslash \backslash$. For instance, to place a percent sign after a statistic, you can specify sformat("\%s\%\%").

## Options

estimates (namelist) specifies the estimation results to be included in the table. These are the names specified with estimates store. By default, etable creates a table with the active estimation results.
margins creates a table with the results of the immediately preceding margins command.
replay specifies that etable redisplay the table without consuming results.
column (column_header) specifies the content to be used in the column headers. column_header may be depvar, dvlabel, command, title, estimates, or index.
depvar specifies that etable use the dependent variable name for the column headers. This name is obtained from the eclass macro e(depvar). Note that this macro may contain multiple names after fitting a multivariate model.
dvlabel specifies that etable use the variable label for the dependent variable name for the column headers. etable uses the variable label associated with the variable name in the eclass macro e(depvar). If the variable does not have a variable label, the variable name will be used. column(dvlabel) will not be helpful when the estimation command stores multiple names in e(depvar).
command specifies that etable use the command name for the column headers. This name is obtained from the eclass macro e(cmd).
title specifies that etable use the command title for the column headers. This title is obtained from the eclass macro e(title).
estimates specifies that etable use the name given to previously stored estimation results for the column headers; these are the names specified with estimates store.
index specifies that etable use the result set index for the column headers.
name (cname) specifies the collection from which estimation results will be obtained, instead of the current collection. The default is name (ETable).
append specifies that etable append the results into the collection named in name().
replace permits etable to overwrite the existing collection. This option is implied for name (ETable)
when append and replay are not specified.

Coefficients
keep (coeflist) specifies the coefficients to be included in the table and the order in which to display them. Names are separated from each other by blanks. The default is to display all coefficients.
cstat (cstat[, cstat_opts]) specifies the coefficient statistic to be included in the table. Optionally, you may specify the label and style for this statistic. cstat () may be repeated to request multiple coefficient statistics.

The default is to display the coefficients ( $\_\mathbf{r} \_$b) and their standard errors ( $\_$r_se), both formatted to three decimals. Standard errors are enclosed in parentheses.

Available coefficient statistics are

| cstat | Description |
| :---: | :---: |
| -r_b | coefficients reported by estimation |
| _r_se | standard errors of _r_b |
| -r_z | test statistics for _r_b |
| -r_z_abs | absolute values of $\_$r $\quad$ z |
| -r_p | $p$-values for $\_$r_b |
| _r_lb | lower bounds of confidence intervals (CIs) for $\quad$ r_b |
| _r_ub | upper bounds of CIs for $\_$r_b |
| _r_ci | CIs for _r_b |
| _r_crlb | lower bounds of credible intervals for _r_b |
| -r_crub | upper bounds of credible intervals for $-r \_b$ |
| _r_cri | credible intervals of Bayesian estimates |
| _hide | hide coefficient statistics |

cstat_opts are label(string), font([fontfamily] [, font_opts]), smcl(smcl), latex (latex), shading (sspec), nformat (\%fmt), sformat (sfmt), cidelimiter(char), and cridelimiter (char).
label (string) is used to modify the label for the specified coefficient statistic.
font ([fontfamily] [, size(\# [unit]) color(color) variant (variant) [no]bold [no]italic [no]strikeout [no]underline underline (upattern)]) specifies the font style for the coefficient statistic. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and LETEX files, unless otherwise specified.
fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
size (\# [unit]) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
color (color) specifies the text color.
variant (variant) specifies the font variant and capitalization.
bold and nobold specify the font weight. bold changes the font weight to bold; nobold changes the font weight back to normal.
italic and noitalic specify the font style. italic changes the font style to italic; noitalic changes the font style back to normal.
strikeout and nostrikeout specify whether to add a strikeout mark to the coefficient statistic. strikeout adds a strikeout mark to the statistic; nostrikeout changes the statistic back to normal.
underline(upattern), underline, and nounderline specify how to underline the coefficient statistic.

Only one of strikeout or underline is allowed when publishing to HTML files.
smcl (smcl) specifies how to render the statistic value for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.
latex (latex) specifies how to render the statistic value for $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ output. This style property is applicable only when publishing items from a collection to a $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ file.
shading (sspec) sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.
nformat (\%fmt) applies the Stata numeric format \% fmt to the coefficient statistic.
sformat (sfint) applies a string format to the coefficient statistic.
cidelimiter (char) changes the delimiter between confidence interval limits for coefficient statistic _r_ci. The default is cidelimiter(" ").
cridelimiter (char) changes the delimiter between credible interval limits for coefficient statistic _r_cri. The default is cridelimiter(" ").
mstat (mstat [, mstat_opts]) specifies the model statistics to be included in the table.
mstat may be a result identifier or a named expression. mstat () may be repeated to request multiple model statistics. The default is to display the number of observations, with zero decimal digits. result identifier is one of the following:

| Identifier | Result |
| :--- | :--- |
| N | number of observations |
| aic | Akaike's information criteria |
| bic | Schwarz's Bayesian information criteria |
| F | $F$ statistic |
| chi2 | $\chi^{2}$ |
| ll | log likelihood of fitted model |
| r2 | $R^{2}$ |
| r2_a | adjusted $R^{2}$ |
| rank | rank of fitted model |
| escalar | any e() scalar, by default |
| rscalar | any r() scalar with option margins |
| _hide | hide model statistics |

named expression is specified as name $=$ exp, where name may be any valid Stata name and exp is a scalar expression, typically an expression that involves one or more scalars in e(). For example, aic $=(-2 * e(l l)+2 * e(r a n k))$.
With option margins, or if you ran a postestimation command like estat, exp may also involve one or more scalars in $r()$. For example, suppose you fit a logistic model and also called estat gof, then you can show its goodness-of-fit statistic with chi2_gof=(r(chi2)).
mstat_opts are label (string), font ([fontfamily] [, font_opts]), smcl (smcl), latex(latex), shading (sspec), nformat (\%fint), and sformat (sfmt).
label (string) is used to modify the label for the specified model statistic.
font ([fontfamily] [, size(\# [unit]) color (color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline underline(upattern)]) specifies the font style for the model statistic. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and LATEX files, unless otherwise specified.
fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
size (\# [unit]) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
color (color) specifies the text color.
variant (variant) specifies the font variant and capitalization.
bold and nobold specify the font weight. bold changes the font weight to bold; nobold changes the font weight back to normal.
italic and noitalic specify the font style. italic changes the font style to italic; noitalic changes the font style back to normal.
strikeout and nostrikeout specify whether to add a strikeout mark to the model statistic. strikeout adds a strikeout mark to the statistic; nostrikeout changes the text back to normal.
underline(upattern), underline, and nounderline specify how to underline the model statistic.

Only one of strikeout or underline is allowed when publishing to HTML files.
$\operatorname{smcl}(s m c l)$ specifies how to render the statistic value for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.
latex (latex) specifies how to render the statistic value for $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ output. This style property is applicable only when publishing items from a collection to a LATEX file.
shading (sspec) sets the background color, foreground color, and fill pattern.
nformat (\% fmt) applies the Stata numeric format \%fmt to the model statistic.
sformat (sfint) applies a string format to the model statistic.

Equations
equations (eqlist) specifies the equations to be included in the table and the order in which they are reported.
eqrecode (oldeq $=$ neweq $)$ changes the equation name from oldeq to neweq. eqrecode() may be repeated to recode multiple equations.
showeq and noshoweq specify whether equations should be displayed. showeq displays the equations; noshoweq suppresses the equations. manages the display of stars for indicating the significance of results.

The default is stars (. 05 "*" . 01 "**", attach (_r_b)), which will display one star (*) for $p$-values less than 0.05 and two stars $(* *)$ for $p$-values less than 0.01 ; the stars will be attached to the coefficients ( $\_$r_b).
stars_opts are attach(cstat), increasing, decreasing, pvname(string), delimiter (char), nformat(\%fmt), prefix(string), suffix(string), and clear.
attach (cstat) specifies that the star labels be attached to coefficient statistic cstat. The default is attach (_r_b).
increasing and decreasing control the order of $p$-values in the stars note.
increasing specifies that the stars note be composed with increasing $p$-values. This is the default.
decreasing specifies that the stars note be composed with decreasing $p$-values.
pvname (string) specifies the name for the $p$-value in the stars note that is displayed with showstarsnote. The default is pvname ( p ).
delimiter (char) changes the delimiter between labels in the stars note. The default is cridelimiter(",").
nformat (\%fmt) specifies the numeric format for the numbers displayed in the stars note. The default is nformat ( $\% 9.0 \mathrm{~g}$ ).
prefix (string) adds a prefix to the stars note.
suffix (string) adds a suffix to the stars note.
clear removes existing star properties.
showstars and noshowstars specify whether star labels should be displayed. showstars displays star labels; noshowstars suppresses the star labels.
showstarsnote and noshowstarsnote specify whether to display the note explaining what the star labels represent. showstarsnote displays the note; noshowstarsnote suppresses the note.
showstarsnote is ignored if noshowstars is in effect.

Title
title (string) adds the text string as a title to the table.
titlestyles(text_styles) changes the style for the table title. text_styles are the following:
font ([fontfamily] [, size(\# [unit]) color (color) variant (variant) [no]bold
[no]italic [no]strikeout [no]underline]) specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and LATEX files, unless otherwise specified.
fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
size (\# [unit]) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
color (color) specifies the text color.
variant (variant) specifies the font variant and capitalization.
bold and nobold specify the font weight. bold changes the font weight to bold; nobold changes the font weight back to normal.
italic and noitalic specify the font style. italic changes the font style to italic; noitalic changes the font style back to normal.
strikeout and nostrikeout specify whether to add a strikeout mark to the title. strikeout adds a strikeout mark to the title; nostrikeout changes the title back to normal.
underline and nounderline specify whether to underline the table title. underline adds a single line under the title; nounderline removes the underline.

Only one of strikeout or underline is allowed when publishing to HTML files.
smcl ( smcl ) specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.
latex (latex) specifies how to render the table title for ${ }^{[A T} T_{E} X$ output. This style property is applicable only when publishing items from a collection to a LATEX file.
shading (sspec) sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and LATEX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.
note (string) adds the text string as a note to the table. note() may be specified multiple times to add multiple notes. Each note is placed on a new line.
notestyles (text_styles) changes the style for the table notes. text_styles are the following:
font ([fontfamily] [, size(\# [unit]) color (color) variant (variant) [no]bold
[no]italic [no]strikeout [no]underline]) specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and LATEX files, unless otherwise specified.
fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
size (\# [unit]) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.
color (color) specifies the text color.
variant (variant) specifies the font variant and capitalization.
bold and nobold specify the font weight. bold changes the font weight to bold; nobold changes the font weight back to normal.
italic and noitalic specify the font style. italic changes the font style to italic; noitalic changes the font style back to normal.
strikeout and nostrikeout specify whether to add a strikeout mark to the notes. strikeout adds a strikeout mark to the note; nostrikeout changes the note back to normal.
underline and nounderline specify whether to underline the table notes. underline adds a single line under the notes; nounderline removes the underline.

Only one of strikeout or underline is allowed when publishing to HTML files.
smcl (smcl) specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.
latex (latex) specifies how to render the table notes for $\mathrm{LT}_{\mathrm{E}} \mathrm{X}$ output. This style property is applicable only when publishing items from a collection to a $\mathrm{EAT}_{\mathrm{E}}$ file.
shading (sspec) sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$ files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export
export (filename.suffix [, export_opts]) exports the table to the specified file. export_opts are the following:
as (fileformat) specifies the file format to which the table is to be exported. This option is rarely specified because, by default, etable determines the format from the suffix of the file being created.
replace permits etable to overwrite an existing file.
noisily specifies that etable show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The putdocx, putexcel, or putpdf command used to export the table will be displayed.
dofile(filename[, replace]) specifies that etable save to filename the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.
If filename already exists, it can be overwritten by specifying replace. If filename is specified without an extension, .do is assumed.
append specifies that etable append the table to an existing file.
This option is applicable when you export the table to an HTML, a LATEX, a SMCL, a txt, or a Markdown file. When you export to HTML and LATEX files, the append option implies the tableonly option. Furthermore, when you export to HTML files, if the target CSS file already exists, etable will also append to it.
tableonly specifies that only the table be exported to the specified HTML or ${ }^{L A T} \mathrm{E}_{\mathrm{E}} \mathrm{X}$ document. By default, etable produces complete HTML and LATEX documents.

When you export to an HTML file, if the cssfile() option is not specified, a CSS filename is constructed from filename, with the extension replaced with .css.
cssfile(cssfile) specifies that etable define the styles in cssfile instead of filename when you export to HTML.
prefix (prefix) specifies that etable use prefix to identify style classes when you export to HTML.
sheet (sheetname [, replace]) saves to the worksheet named sheetname. For more information about this option, see [RPT] putexcel.
cell (cell) specifies an Excel upper-left cell as the starting position to publish the table. The default is cell(A1).
modify permits putexcel set to modify an Excel file. For more information about this option, see [RPT] putexcel.
noopen prevents putexcel from opening the Excel file in memory for modification. It does not appear on the dialog box. For more information about this option, see [RPT] putexcel. This
option is necessary only when you need to force etable to produce do-files as it did when etable was first introduced in Stata 17.
$\qquad$
varlabel and novarlabel specify whether variable labels should be displayed. varlabel displays variable labels; novarlabel displays variable names.
fvlabel and nofvlabel specify whether value labels should be displayed. fvlabel displays value labels; nofvlabel displays the values of the factor variable.
center and nocenter specify how item cells are horizontally aligned. center specifies that item cells are centered; nocenter specifies that item cells are right-aligned.
label (filename [, replace]) specifies the filename containing the collection labels to use for your table. Labels in filename will be loaded for the table, and default labels will be used for any labels not specified in filename.

If you prefer to replace the labels used by etable with those specified in filename, specify replace. The etable labels will be discarded, and only the labels in filename will be applied.
style(filename[, override]) specifies the filename containing the collection styles to use for your table. This might be a style you saved with collect style save or a predefined style shipped with Stata. The etable collection styles will be discarded, and only the collection styles in filename will be applied. Note that the layout specification saved in filename will not be applied; etable will always use its predefined layout.

If you prefer the etable collection styles but also want to apply any styles in filename, specify override. If there are conflicts between the default collection styles and those in filename, the ones in filename will take precedence.

The default is to use only the collection styles set in c(etable_style); see [TABLES] set etable_style.

The following option is available with etable but is not shown in the dialog box:
warn specifies that etable display warnings from collect. By default, these warnings are suppressed.

## Remarks and examples

Remarks are presented under the following headings:
Introduction
A first example
Table comparing regression results
Multiple-equation models

## Introduction

etable allows you to easily create a table of estimation results and export it to a variety of file types, without any knowledge of the collection system. You can make a standard estimation table with the active estimation results, results from a margins command, or with stored estimates. You can also customize the table by formatting the results, adding model statistics and coefficient-specific statistics, labeling statistically significant results, adding a title and notes, and more.

In most cases, you will use etable to easily create a table and export it to another format. However, you can customize the table beyond the options that are available with etable. When you issue an etable command, the results are stored in a collection called ETable. This collection is replaced with each new etable command, unless you specify the append or replay option. You can make additional changes to the collection with the collect suite of commands. To learn more about the collect commands, see [TABLES] Intro and the entries discussed therein.

## A first example

In its simplest specification, you type etable after fitting a model, and you get a table with coefficients, standard errors, and the number of observations. For example, below, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). We fit a simple model for systolic blood pressure and then create our table of estimation results:

```
. use https://www.stata-press.com/data/r18/nhanes2l
(Second National Health and Nutrition Examination Survey)
. quietly: regress bpsystol age weight i.region
. etable
```

|  | bpsystol |
| :--- | ---: |
| Age (years) | 0.638 |
|  | $(0.011)$ |
| Weight (kg) | 0.407 |
|  | $(0.012)$ |
| Region | -0.240 |
| MW | $(0.564)$ |
| S | -0.619 |
|  | $(0.560)$ |
| W | -0.862 |
|  | $(0.570)$ |
| Intercept | 71.708 |
|  | $(1.108)$ |
| Number of observations | 10351 |

You can also include statistics that pertain to the coefficients, such as test statistics and confidence intervals, and model statistics, such as the $R^{2}$ value and the $F$ statistic. You can look at the cstat () and mstat () options for additional statistics.

Additionally, you can complete your table with a title, notes, and labels for significant results. For example, below, we add a title to our table, and we display stars for statistically significant results:

```
. etable, title(Model for systolic blood pressure) showstars showstarsnote
Model for systolic blood pressure
\begin{tabular}{lc}
\hline & bpsystol \\
\hline Age (years) & \(0.638)^{* *}\) \\
Weight (kg) & \((0.011)\) \\
& \(0.407)^{* *}\) \\
Region & \((0.012)\) \\
MW & -0.240 \\
S & \((0.564)\) \\
& -0.619 \\
W & \((0.560)\) \\
& -0.862 \\
Intercept & \((0.570)\) \\
& \(71.708 * *\) \\
Number of observations & \((1.108)\) \\
\hline
\end{tabular}
** p<.01, * p<.05
```

The showstars option displays stars next to the coefficients that are significant either at the $1 \%$ or $5 \%$ levels, and showstarsnote adds the note we see at the bottom, explaining what the stars represent. You can look at the stars() option to create your own rules for displaying stars or to specify your own labels for significance.

Suppose we have finalized our table and we are ready to export it to another format. Below, we export our table to the file mytable.html:

```
. etable, title(Model for systolic blood pressure)
> showstars showstarsnote export(mytable.html)
Model for systolic blood pressure
\begin{tabular}{lc} 
& bpsystol \\
\hline Age (years) & \(0.638 * *\) \\
Weight (kg) & \((0.011)\) \\
\(0.407 * *\) \\
Region & \((0.012)\) \\
MW & -0.240
\end{tabular}
    (0.564)
    S -0.619
                                    (0.560)
    W -0.862
        (0.570)
Intercept 71.708 *
    (1.108)
Number of observations 10351
** p<.01, * p<.05
(collection ETable exported to file mytable.html)
```

We could also export this table to a Microsoft Word, Microsoft Excel, LATEX, Markdown, SMCL, PDF, or plain text file by specifying the appropriate file extension.

## Table comparing regression results

If your goal is to create a table comparing regression results, you can store the results from each model with estimates store and then specify which of those models you want to include in your table with the estimates() option.

For example, below, we fit two different models for systolic blood pressure and store them under the names model1 and model2.
. quietly: regress bpsystol i.sex weight
. estimates store model1
. quietly: regress bpsystol i.sex i.agegrp weight
. estimates store model2
To include results from both of these models in our table, we specify estimates (model1 model2); the models are presented in the order we list them. Additionally, we report the number of observations and the $R^{2}$ adjusted for degrees of freedom.

```
. etable, estimates(model1 model2) mstat(N) mstat(r2_a)
```

|  | bpsystol bpsystol |  |
| :---: | :---: | :---: |
| Sex |  |  |
| Female | 1.420 | 1.041 |
|  | (0.475) | (0.415) |
| Weight (kg) | 0.452 | 0.436 |
|  | (0.015) | (0.014) |
| Age group |  |  |
| 30-39 |  | 1.195 |
|  |  | (0.633) |
| 40-49 |  | 7.252 |
|  |  | (0.684) |
| 50-59 |  | 15.942 |
|  |  | (0.681) |
| 60-69 |  | 22.839 |
|  |  | (0.546) |
| 70+ |  | 30.466 |
|  |  | (0.741) |
| Intercept | 97.634 | 86.710 |
|  | (1.246) | (1.116) |
| Number of observations | 10351 | 10351 |
| Adjusted R-squared | 0.08 | 0.30 |

We would like to make a few changes to finalize this table. First, because both models have the same dependent variable, we want to display the index of result sets instead of the variable name. Second, we add stars for significance and a note explaining what the stars represent. Third, instead of reporting standard errors, we want to report confidence intervals (_r_ci). We format the intervals with one decimal place and use a comma as the delimiter. etable will automatically report coefficients, unless you specify cstat (), in which case it will report only the coefficient statistics you specify; therefore, we add cstat (_r_b). Finally, we add a title to our table:

```
. etable, estimates(model1 model2) mstat(N) mstat(r2_a) column(index)
> showstars showstarsnote cstat(_r_b)
> title("Models for systolic blood pressure")
> cstat(_r_ci, nformat(%6.1f) cidelimiter(","))
Models for systolic blood pressure
```

|  |  | 1 |  |  | 2 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Sex |  |  |  |  |  |  |
| Female |  | 1.420 | ** |  | 1.041 | * |
|  | [0.5, | $2.4]$ |  | [0.2, | 1.9] |  |
| Weight (kg) |  | 0.452 | ** |  | 0.436 | ** |
|  | [0.4, | 0.5] |  | [0.4, | 0.5] |  |
| Age group |  |  |  |  |  |  |
| 30-39 |  |  |  |  | 1.195 |  |
|  |  |  |  | [-0.0, | 2.4] |  |
| 40-49 |  |  |  |  | 7.252 | ** |
|  |  |  |  | [5.9, | 8.6] |  |
| 50-59 |  |  |  |  | 15.942 | ** |
|  |  |  |  | [14.6, | 17.3] |  |
| 60-69 |  |  |  |  | 22.839 | ** |
|  |  |  |  | [21.8, | $23.9]$ |  |
| 70+ |  |  |  |  | 30.466 | ** |
|  |  |  |  | [29.0, | 31.9] |  |
| Intercept |  | 97.634 | ** |  | 86.710 | ** |
|  | [95.2, | 100.1] |  | [84.5, | 88.9] |  |
| Number of observations |  | 10351 |  |  | 10351 |  |
| Adjusted R-squared |  | 0.08 |  |  | 0.30 |  |

Now our table is complete.
An alternative way to create this table is to build up the estimation table with the append option. For example, we can fit the first model and create the table. Then, after fitting the second model, we append the results as follows:

```
. quietly: regress bpsystol i.sex weight
. etable
. quietly: regress bpsystol i.sex i.agegrp weight
. etable, append mstat(N) mstat(r2_a) column(index)
> showstars showstarsnote cstat(_r_b)
> title("Models for systolic blood pressure")
> cstat(_r_ci, nformat(%6.1f) cidelimiter(","))
    (output omitted)
```

## Multiple-equation models

When you work with multiple-equation models, there is an additional option that will prove useful when creating the table of estimation results. For example, below, we fit a multivariate regression with mvreg:
. mvreg bpsystol bpdiast = age weight

| Equation | Obs | Parms | RMSE | "R-sq" | F | P>F |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| bpsystol | 10,351 | 3 | 19.48051 | 0.3031 | 2250 | 0.0000 |
| bpdiast | 10,351 | 3 | 11.51474 | 0.2067 | 1348.469 | 0.0000 |

|  | Coefficient | Std. err. | t | $\mathrm{P}>\mid \mathrm{t\mid}$ | [95\% conf. interval] |  |
| ---: | ---: | :--- | :---: | :---: | :---: | :---: |
| bpsystol |  |  |  |  |  |  |
| age | .6379892 | .0111315 | 57.31 | 0.000 | .6161692 | .6598091 |
| weight | .4069041 | .0124786 | 32.61 | 0.000 | .3824435 | .4313646 |
| _cons | 71.27096 | 1.041742 | 68.42 | 0.000 | 69.22894 | 73.31297 |
| bpdiast |  |  |  |  |  |  |
| age | .187733 | .0065797 | 28.53 | 0.000 | .1748355 | .2006306 |
| weight | .3116502 | .007376 | 42.25 | 0.000 | .2971918 | .3261086 |
| _cons | 50.37585 | .615764 | 81.81 | 0.000 | 49.16884 | 51.58287 |

Next, we create our table of estimation results:
. etable

|  | bpsystol bpdiast |
| :---: | :---: |
| Age (years) | 0.638 |
|  | (0.011) |
| Weight (kg) | 0.407 |
|  | (0.012) |
| Intercept | 71.271 |
|  | (1.042) |
| Age (years) | 0.188 |
|  | (0.007) |
| Weight (kg) | 0.312 |
|  | (0.007) |
| Intercept | 50.376 |
|  | (0.616) |
| Number of observations | 10351 |

The results for both models are placed in a single column, so below we add the showeq option to display the equation names (bpsystol and bpdiast). This will help us identify which results correspond to each model. Note that there are two dependent variables in this model, and both variable names are displayed in the column header. These names are collected from the returned result e (depvar). Instead of displaying both names, we will display the index of result sets we have collected for our table by typing command (index).

| . etable, showeq column(index) |  |
| :--- | ---: |
|  | 1 |
| Systolic blood pressure |  |
| Age (years) | 0.638 |
|  | $(0.011)$ |
| Weight (kg) | 0.407 |
|  | $(0.012)$ |
| Intercept | 71.271 |
|  | $(1.042)$ |
| Diastolic blood pressure | 0.188 |
| Age (years) | $(0.007)$ |
|  | 0.312 |
| Weight (kg) | $(0.007)$ |
|  | 50.376 |
| Intercept | $(0.616)$ |
|  | 10351 |

[R] table intro - Introduction to tables of frequencies, summaries, and command results [TABLES] Intro - Introduction

## Title

exit — Exit Stata

## Description Syntax Option Remarks and examples Also see

## Description

Typing exit causes Stata to stop processing and return control to the operating system. If the dataset in memory has changed since the last save command, you must specify the clear option before Stata will let you exit.

If you wish to use exit in do-files or programs to set return codes or terminate programs, see [ P ] exit.

Stata for Windows users may also exit Stata by clicking on the Close button or by pressing Alt + F4.
Stata for Mac users may also exit Stata by pressing Command+Q.
Stata for Unix(GUI) users may also exit Stata by clicking on the Close button.

## Syntax

```
exit [, clear]
```

## Option

clear permits you to exit, even if the current dataset has not been saved.

## Remarks and examples

Type exit to leave Stata and return to the operating system. If the dataset in memory has changed since the last time it was saved, however, Stata will refuse. At that point, you can either save the dataset and then type exit, or type exit, clear:

```
. exit
no; dataset in memory has changed since last saved
r(4);
. exit, clear
```

## Title

exlogistic - Exact logistic regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

exlogistic fits an exact logistic regression model, which produces more accurate inference in small samples than the standard maximum-likelihood-based logistic regression estimator. It can also better deal with completely determined outcomes. exlogistic with the group() option conditions on the number of positive outcomes within stratum and is an alternative to the conditional (fixed-effects) logistic regression estimator.

Unlike Stata's other estimation commands, exlogistic must perform hypothesis tests during estimation rather than after estimation with standard postestimation commands.

## Quick start

Exact logistic regression of y on $\mathrm{x} 1, \mathrm{x} 2$, and x 3
exlogistic y x1 x2 x3
Same as above, but condition on values of $x 3$ to save time and memory

```
exlogistic y x1 x2, condvars(x3)
```

Same as above, and allow more memory for computing the conditional distribution of sufficient statistics
exlogistic y x1 x2, condvars(x3) memory (100m)
Using data stored in binomial form with ys successes out of n trials
exlogistic ys x1 x2 x3, binomial(n)
Report coefficients rather than odds ratios
exlogistic y x1 x2 x3, coef
Report conditional scores tests
exlogistic y x1 x2 x3, test(score)
Fit a model with strata identified by svar
exlogistic y x1 x2 x3, group(svar)

## Menu

Statistics $>$ Exact statistics $>$ Exact logistic regression

## Syntax

exlogistic depvar indepvars [if] [in] [weight] [, options]
depvar can be specified as a zero or nonzero variable or the number of positive outcomes within each trial. For a zero or nonzero variable, zero indicates failure and nonzero indicates success. To specify depvar as the number of positive outcomes, you must also specify binomial (varname|\#).

## options

Model
condvars (varlist ${ }_{c}$ )
group (varname)
binomial (varname|\#)
estconstant
noconstant
Options
memory (\# $[\mathrm{b}|\mathrm{k}| \mathrm{m} \mid \mathrm{g}]$ ) set limit on memory usage; default is memory ( 10 m )
saving (filename [, replace]) save the joint conditional distribution to filename

Description
condition on variables in varlist $_{c}$
groups or strata are stratified by unique values of varname data are in binomial form and the number of trials is contained in varname or in \#
estimate constant term; do not condition on the number of successes
suppress constant term
set confidence level; default is level (95)
report estimated coefficients
report $p$-value for observed sufficient statistic, conditional scores test, or conditional probabilities test
compute the median unbiased estimates for varlist $_{m}$ use the mid- $p$-value rule
display or suppress the enumeration log; default is to display control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
display legend instead of statistics
indepvars, varlist $_{c}$, and varlist ${ }_{m}$ may contain factor variables; see [U] 11.4.3 Factor variables.
by, collect, and statsby are allowed; see [U] 11.1.10 Prefix commands.
fweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

> Model
> condvars ( varlist $_{c}$ ) specifies variables whose parameter estimates are not of interest to you. You can save substantial computer time and memory by moving such variables from indepvars to condvars (). Understand that you will get the same results for $x 1$ and $x 3$ whether you type
or
. exlogistic y x1 x3, condvars(x2 x4)
group (varname) specifies the variable defining the strata, if any. A constant term is assumed for each stratum identified in varname, and the sufficient statistics for indepvars are conditioned on the observed number of successes within each group. This makes the fitted model equivalent to that fit by clogit, Stata's conditional logistic regression command (see [R] clogit). group() may not be specified with estconstant or noconstant.
binomial (varname |\#) indicates that the data are in binomial form and depvar contains the number of successes. varname contains the number of trials for each observation. If all observations have the same number of trials, you can instead specify the number as an integer. The number of trials must be a positive integer at least as great as the number of successes. If binomial () is not specified, the data are assumed to be Bernoulli, meaning that depvar equaling zero or nonzero records one failure or success.
estconstant estimates the constant term. By default, the models are assumed to have an intercept (constant), but the value of the intercept is not calculated. That is, the conditional distribution of the sufficient statistics for the indepvars is computed given the number of successes in depvar, thus conditioning out the constant term of the model. Use estconstant if you want the estimate of the intercept reported. estconstant may not be specified with group().
noconstant; see [R] Estimation options. noconstant may not be specified with group().

Options
memory (\# $[\mathrm{b}|\mathrm{k}| \mathrm{m} \mid \mathrm{g}]$ ) sets a limit on the amount of memory exlogistic can use when computing the conditional distribution of the parameter sufficient statistics. The default is memory $(10 \mathrm{~m})$, where m stands for megabyte, or $1,048,576$ bytes. The following are also available: b stands for byte; k stands for kilobyte, which is equal to 1,024 bytes; and g stands for gigabyte, which is equal to 1,024 megabytes. The minimum setting allowed is 1 m , and the maximum is 2048 m or 2 g , but do not attempt to use more memory than is available on your computer. Also see the first technical note under example 4 on counting the conditional distribution.
saving (filename [, replace]) saves the joint conditional distribution to filename. This distribution is conditioned on those variables specified in condvars(). Use replace to replace an existing file with filename. A Stata data file is created containing all the feasible values of the parameter sufficient statistics. The variable names are the same as those in indepvars, in addition to a variable named _f_ containing the feasible value frequencies (sometimes referred to as the condition numbers).

## Reporting

level(\#); see [R] Estimation options. The level() option will not work on replay because confidence intervals are based on estimator-specific enumerations. To change the confidence level, you must refit the model.
coef reports the estimated coefficients rather than odds ratios (exponentiated coefficients). coef may be specified when the model is fit or upon replay. coef affects only how results are displayed and not how they are estimated.
test (sufficient |score $\mid$ probability) reports the $p$-value associated with the observed sufficient statistics, the conditional scores tests, or the conditional probabilities tests, respectively. The default is test (sufficient). If factor variables are included in the specification, the conditional scores test and the conditional probabilities test are applied to each term providing conditional inference for several parameters simultaneously. All the statistics are computed at estimation time regardless
of which is specified. Each statistic may thus also be displayed when replaying results after estimation without having to refit the model; see $[\mathrm{R}]$ exlogistic postestimation.
mue ( varlist $_{m}$ ) specifies that median unbiased estimates (MUEs) be reported for the specified variables. By default, the conditional maximum likelihood estimates (CMLEs) are reported, except for those parameters for which the CMLEs are infinite. Specify mue (_all) if you want MUEs for all the indepvars.
midp instructs exlogistic to use the mid- $p$-value rule when computing the MUEs, $p$-values, and confidence intervals. This adjustment is for the discreteness of the distribution and halves the value of the discrete probability of the observed statistic before adding it to the $p$-value. The mid- $p$-value rule cannot be applied to MUEs whose corresponding parameter CMLE is infinite.
log and nolog specify whether to display the enumeration log, which shows the progress of computing the conditional distribution of the sufficient statistics. The enumeration $\log$ is displayed by default unless you used set iterlog off to suppress it; see set iterlog in [R] set iter.
display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), and sformat (\% firt); see [R] Estimation options.

Note that the maximum widths for cformat(), pformat(), and sformat() differ from those widths listed in [R] Estimation options. The maximum width for each format is 9 for exlogistic.

The following option is available with exlogistic but is not shown in the dialog box:
coeflegend; see [R] Estimation options.

## Remarks and examples

Exact logistic regression is the estimation of the logistic model parameters by using the conditional distribution of the parameter sufficient statistics. The estimates are referred to as the conditional maximum likelihood estimates (CMLEs). This technique was first introduced by Cox and Snell (1989) as an alternative to using maximum likelihood estimation, which can perform poorly for small sample sizes. For stratified data, exact logistic regression is a small-sample alternative to conditional logistic regression. See $[R]$ logit, $[R]$ logistic, and $[R]$ clogit to obtain maximum likelihood estimates (MLEs) for the logistic model and the conditional logistic model. For a comprehensive overview of exact logistic regression, see Mehta and Patel (1995).

Let $Y_{i}$ denote a Bernoulli random variable where we observe the outcome $Y_{i}=y_{i}, i=1, \ldots, n$. Associated with each independent observation is a $1 \times p$ vector of covariates, $\mathbf{x}_{i}$. We will denote $\pi_{i}=\operatorname{Pr}\left(Y_{i} \mid \mathbf{x}_{i}\right)$ and let the logit function model the relationship between $Y_{i}$ and $\mathbf{x}_{i}$,

$$
\log \left(\frac{\pi_{i}}{1-\pi_{i}}\right)=\theta+\mathbf{x}_{i} \boldsymbol{\beta}
$$

where the constant term $\theta$ and the $p \times 1$ vector of regression parameters $\boldsymbol{\beta}$ are unknown. The probability of observing $Y_{i}=y_{i}, i=1, \ldots, n$, is

$$
\operatorname{Pr}(\mathbf{Y}=\mathbf{y})=\prod_{i=1}^{n} \pi_{i}^{y_{i}}\left(1-\pi_{i}\right)^{1-y_{i}}
$$

where $\mathbf{Y}=\left(Y_{1}, \ldots, Y_{n}\right)$ and $\mathbf{y}=\left(y_{1}, \ldots, y_{n}\right)$. The MLEs for $\theta$ and $\boldsymbol{\beta}$ maximize the log of this function.

The sufficient statistics for $\theta$ and $\beta_{j}, j=1, \ldots, p$, are $M=\sum_{i=1}^{n} Y_{i}$ and $T_{j}=\sum_{i=1}^{n} Y_{i} x_{i j}$, respectively, and we observe $M=m$ and $T_{j}=t_{j}$. By default, exlogistic tallies the conditional distribution of $\mathbf{T}=\left(T_{1}, \ldots, T_{p}\right)$ given $M=m$. This distribution will have a size of $\binom{n}{m}$. (It would have a size of $2^{n}$ without conditioning on $M=m$.) Denote one of these vectors $\mathbf{T}^{(k)}=$ $\left(t_{1}^{(k)}, \ldots, t_{p}^{(k)}\right), k=1, \ldots, N$, with combinatorial coefficient (frequency) $c_{k}, \sum_{k=1}^{N} c_{k}=\binom{n}{m}$. For each independent variable $x_{j}, j=1, \ldots, p$, we reduce the conditional distribution further by conditioning on all other observed sufficient statistics $T_{l}=t_{l}, l \neq j$. The conditional probability of observing $T_{j}=t_{j}$ has the form

$$
\operatorname{Pr}\left(T_{j}=t_{j} \mid T_{l}=t_{l}, l \neq j, M=m\right)=\frac{c e^{t_{j} \beta_{j}}}{\sum_{k} c_{k} e^{t_{j}^{(k)} \beta_{j}}}
$$

where the sum is over the subset of $\mathbf{T}$ vectors such that $\left(T_{1}^{(k)}=t_{1}, \ldots, T_{j}^{(k)}=t_{j}^{(k)}, \ldots, T_{p}^{(k)}=t_{p}\right)$ and $c$ is the combinatorial coefficient associated with the observed $\mathbf{t}$. The CMLE for $\beta_{j}$ maximizes the $\log$ of this function.

Specifying nuisance variables in condvars() will reduce the size of the conditional distribution by conditioning on their observed sufficient statistics as well as conditioning on $M=m$. This reduces the amount of memory consumed at the cost of not obtaining regression estimates for those variables specified in condvars().

Inferences from MLEs rely on asymptotics, and if your sample size is small, these inferences may not be valid. On the other hand, inferences from the CMLEs are exact in that they use the conditional distribution of the sufficient statistics outlined above.

For small datasets, the dependent variable can be completely determined by the data. Here the MLEs and the CMLEs are unbounded. When this occurs, exlogistic will compute the MUE, the regression estimate that places the observed sufficient statistic at the median of the conditional distribution.

## > Example 1

One example presented by Mehta and Patel (1995) is data from a prospective study of perinatal infection and human immunodeficiency virus type 1 (HIV-1). We use a variation of this dataset. There was an investigation (Hutto et al. 1991) into whether the blood serum levels of glycoproteins CD4 and CD8 measured in infants at 6 months of age might predict their development of HIV infection. The blood serum levels are coded as ordinal values 0,1 , and 2 .

```
. use https://www.stata-press.com/data/r18/hiv1
(Prospective study of perinatal infection of HIV-1)
. list in 1/5
```

| hiv | cd4 | cd8 |
| ---: | ---: | ---: |
| Positive | 0 | 0 |
| Negative | 0 | 0 |
| Positive | 0 | 2 |
| Positive | 1 | 0 |
| Negative | 1 | 0 |

We first obtain the MLEs from logistic so that we can compare the estimates and associated statistics with the CMLEs from exlogistic.

exlogistic produced a $\log$ showing how many records are generated as it processes each observation. The primary purpose of the $\log$ is to provide feedback because generating the distribution can be time consuming, but we also see from the last entry that the joint distribution for the sufficient statistics for cd 4 and cd8 conditioned on the total number of successes has 326 unique values (but a size of $\left.\binom{47}{14}=341,643,774,795\right)$.

The statistics for logistic are based on asymptotics: for a large sample size, each $Z$ statistic will be approximately normally distributed (with a mean of zero and a standard deviation of one) if the associated regression parameter is zero. The question is whether a sample size of 47 is large enough.

On the other hand, the $p$-values computed by exlogistic are from the conditional distributions of the sufficient statistics for each parameter given the sufficient statistics for all other parameters. In this sense, these $p$-values are exact. By default, exlogistic reports the sufficient statistics for the regression parameters and the probability of observing a more extreme value. These are singleparameter tests for $H_{0}: \beta_{\mathrm{cd} 4}=0$ and $H_{0}: \beta_{\mathrm{cd} 8}=0$ versus the two-sided alternatives. The conditional scores test, located in the coefficient table header, is testing that both $H_{0}: \beta_{\mathrm{cd} 4}=0$ and $H_{0}: \beta_{\mathrm{cd} 8}=0$. We find these $p$-values to be in fair agreement with the Wald and likelihood-ratio tests from logistic.

The confidence intervals for exlogistic are computed from the exact conditional distributions. The exact confidence intervals are asymmetrical about the estimate and are wider than the normal-based confidence intervals from logistic.

Both estimation techniques indicate that the incidence of HIV infection decreases with increasing CD4 blood serum levels and increases with increasing CD8 blood serum levels. The constant term is
missing from the exact logistic coefficient table because we conditioned out its observed sufficient statistic when tallying the joint distribution of the sufficient statistics for the cd4 and cd8 parameters.

The test () option provides two other test statistics used in exact logistic regression: the conditional scores test, test (score), and the conditional probabilities test, test (probability). For comparison, we display the individual parameter conditional scores tests.

| Exact logistic regression |  |  |  | Number of obs <br> Model score <br> Pr >= score | $\begin{array}{lr} = & 47 \\ = & 13.34655 \\ = & 0.0006 \end{array}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| hiv | Coefficient | Score | Pr $>=$ Score | [95\% conf. | interval] |
| cd4 | -2.387632 | 12.88022 | 0.0003 | -4.699633 | -. 8221807 |
| cd8 | 1.592366 | 4.604816 | 0.0410 | -. 0137905 | 3.907876 |

For the probabilities test, the probability statistic is computed from (1) in Methods and formulas with $\boldsymbol{\beta}=0$. For this example, the $p$-value for the conditional probabilities tests matches the conditional scores tests, so they are not displayed here.

## - Technical note

Typically, the value of $\theta$, the constant term, is of little interest, as well as perhaps some of the parameters in $\boldsymbol{\beta}$, but we need to include all parameters in the model to correctly specify it. By conditioning out the nuisance parameters, we can reduce the size of the joint conditional distribution that is used to estimate the regression parameters of interest. The condvars () option allows you to specify a varlist of nuisance variables. By default, exlogistic conditions on the sufficient statistic of $\theta$, which is the number of successes. You can save computation time and computer memory by using the condvars() option because infeasible values of the sufficient statistics associated with the variables in condvars () can be omitted from consideration before all $n$ observations are processed.

Specifying some of your independent variables in condvars() will not change the estimated regression coefficients of the remaining independent variables. For instance, in example 1, if we instead type
. exlogistic hiv cd4, condvars(cd8) coef
the regression coefficient for $\mathrm{cd4}$ (as well as all associated inference) will be identical.

- Technical note

If you fit a clogit (see [R] clogit) model to the HIV data from example 1, you will find that the estimates differ from those with exlogistic. (To fit the clogit model, you will have to create a group variable that includes all observations.) The regression estimates will be different because clogit conditions on the constant term only, whereas the estimates from exlogistic condition on the sufficient statistic of the other regression parameter as well as the constant term.

## Example 2

The HIV data presented in table IV of Mehta and Patel (1995) are in a binomial form, where the variable hiv contains the HIV cases that tested positive and the variable $n$ contains the number of individuals with the same CD4 and CD8 levels, the binomial number-of-trials parameter. Here depvar is hiv, and we use the binomial(n) option to identify the number-of-trials variable.

```
. use https://www.stata-press.com/data/r18/hiv_n
(Prospective study of perinatal infection of HIV-1; binomial form)
. list
```

| cd4 | cd8 | hiv | n |
| ---: | ---: | ---: | ---: |
| 0 | 2 | 1 | 1 |
| 1 | 2 | 2 | 2 |
| 0 | 0 | 4 | 7 |
| 1 | 1 | 4 | 12 |
| 2 | 2 | 1 | 3 |
| 1 | 0 | 2 | 7 |
| 2 | 0 | 0 | 2 |
| 2 | 1 | 0 | 13 |

Further, the cd4 and cd8 variables are coded with ordinal values $(0,1,2)$. Another approach is to specify these variables as factor variables in the model so that indicators for all but the base level of cd4 and of cd8 will be included in the model. Similar to Mehta and Patel (1995), we will estimate the odds ratio of level 0 versus 2 and level 1 versus 2 by typing ib2.cd4 and ib2.cd8, indicating that 2 is the base level.

```
(*) median unbiased estimates (MUE)
. matrix list e(sufficient)
e(sufficient)[1,6]
            0. 1. 2b. 0. 1. 2b.
        cd4
. display e(n_possible)
1091475
```

Because we included cd4 and cd8 as factor variables, we obtained a conditional probabilities test for cd4, simultaneously testing both $0 . \operatorname{cd4}$ and $1 . c d 4$, and for cd8, simultaneously testing both $0 . c d 8$ and $1 . c d 8$. The $p$-values for the two terms are 0.0055 and 0.0323 , respectively.

This example also illustrates instances where the dependent variable is completely determined by the independent variables and CMLEs are infinite. If we try to obtain MLEs, logistic will omit each variable and then terminate with a no-data error, error number 2000.

```
. use https://www.stata-press.com/data/r18/hiv_n, clear
(Prospective study of perinatal infection of HIV-1; binomial form)
. expand n
(39 observations created)
```

. capture logistic hiv ib2.cd4 ib2.cd8

The previous exlogistic command generated the joint conditional distribution of $T_{0 . \operatorname{cd} 4}, T_{1 . \operatorname{cd} 4}$, $T_{0 . c d 8}$, and $T_{1 . \mathrm{cd} 8}$ given $M=14$ (the number of individuals that tested positive), and for reference, we listed the observed sufficient statistics that are stored in the matrix e(sufficient). Below, we take that distribution and further condition on $T_{1 . \mathrm{cd} 4}=8, T_{0 . \mathrm{cd} 8}=6$, and $T_{1 . \mathrm{cd} 8}=4$, giving the conditional distribution of $T_{0 . c d 4}$. Here we see that the observed sufficient statistic $T_{0 . c d 4}=5$ is last in the sorted listing or, equivalently, $T_{0 . c d 4}$ is at the domain boundary of the conditional probability distribution. When this occurs, the conditional probability distribution is monotonically increasing in $\beta_{0 . c d 4}$ and a maximum does not exist.

```
. use dist, clear
. keep if __1_cd4==8 & _0_cd8==6 & _1_cd8==4
(4,139 observations deleted)
. list, sep(0)
```

| _f_ | _0_cd4 | _1_cd4 | _0_cd8 | _1_cd8 | _2b_cd4 | _2b_cd8 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1668667 | 0 | 8 | 6 | 4 | 0 | 0 |
| 18945542 | 1 | 8 | 6 | 4 | 0 | 0 |
| 55801053 | 2 | 8 | 6 | 4 | 0 | 0 |
| 55867350 | 3 | 8 | 6 | 4 | 0 | 0 |
| 17423175 | 4 | 8 | 6 | 4 | 0 | 0 |
| 1091475 | 5 | 8 | 6 | 4 | 0 | 0 |

When the CMLEs are infinite, the MUEs are computed (Hirji, Tsiatis, and Mehta 1989). For the 0.cd4 estimate, we compute the value $\bar{\beta}_{0 . c d 4}$ such that

$$
\operatorname{Pr}\left(T_{0 . \mathrm{cd} 4} \geq 5 \mid \beta_{0 . \mathrm{cd} 4}=\bar{\beta}_{0 . \mathrm{cd} 4}, T_{1 . \mathrm{cd} 4}=8, T_{0 . \mathrm{cd} 8}=6, T_{1 . \mathrm{cd} 8}=4, M=14\right)=1 / 2
$$

using (1) in Methods and formulas.
The output is in agreement with example 1: there is an increase in risk of HIV infection for a CD4 blood serum level of 0 relative to a level of 2 and for a level of 1 relative to a level of 2 ; there is a decrease in risk of HIV infection for a CD8 blood serum level of 0 relative to a level of 2 and for a level of 1 relative to a level of 2.

We also displayed e(n_possible). This is the combinatorial coefficient associated with the observed sufficient statistics. The same value is found in the _f_ variable of the conditional distribution dataset listed above. The size of the distribution is $\binom{47}{14}=341,643,774,795$. This can be verified by summing the $\mathrm{f}_{\text {_ }}$ variable of the generated conditional distribution dataset.

```
. use dist, clear
. summarize _f_, meanonly
. di %15.1f r(sum)
341643774795.0
```

## > Example 3

One can think of exact logistic regression as a covariate-adjusted exact binomial. To demonstrate this point, we will use exlogistic to compute a binomial confidence interval for $m$ successes of $n$ trials by fitting the constant-only model, and we will compare it with the confidence interval computed by ci proportions (see [R] ci). We will use the saving() option to retain the dataset containing the feasible values for the constant term sufficient statistic, namely, the number of successes, $m$, given $n$ trials and their associated combinatorial coefficients $\binom{n}{m}, m=0,1, \ldots, n$.
. input y
y

| Variable | Obs | Proportion |  | Std. err. | [95\% conf. interval] exact |  |
| ---: | ---: | ---: | ---: | ---: | ---: | :---: |
| $y$ | 6 | .6666667 | .1924501 | .2227781 | .9567281 |  |

. exlogistic y, estconstant nolog coef saving(binom)
note: saving distribution to file binom.dta.
Exact logistic regression

$$
\text { Number of obs }=6
$$

| $y$ | Coefficient | Suff. | $2 * \operatorname{Pr}($ Suff. $)$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| _cons | .6931472 | 4 | 0.6875 | -1.24955 | 3.096017 |

We use the postestimation command estat predict to transform the estimated constant term and its confidence bounds by using the inverse logit function, invlogit() (see [FN] Mathematical functions). The standard error for the estimated probability is computed using the delta method.
. estat predict

| $y$ | Predicted | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | :---: | ---: | ---: |
| Probability | 0.6667 | 0.1925 | 0.2228 | 0.9567 |

. use binom, replace
. list, sep(0)

| -f | _cons_ |
| ---: | ---: |
| 1 | 0 |
| 6 | 1 |
| 15 | 2 |
| 20 | 3 |
| 15 | 4 |
| 6 | 5 |
| 1 | 6 |

Examining the listing of the generated data, the values contained in the variable _cons_ are the feasible values of $M$, and the values contained in the variable $\_\mathrm{f}$ - are the binomial coefficients $\binom{6}{m}$ with total $\sum_{m=0}^{6}\binom{6}{m}=2^{6}=64$. In the coefficient table, the sufficient statistic for the constant term, labeled Suff., is $m=4$. This value is located at record 5 of the dataset. Therefore, the two-tailed probability of the sufficient statistic is computed as $0.6875=2(15+6+1) / 64$.

The constant term is the value of $\theta$ that maximizes the probability of observing $M=4$; see (1) of Methods and formulas:

$$
\operatorname{Pr}(M=4 \mid \theta)=\frac{15 e^{4 \alpha}}{1+6 e^{\alpha}+15 e^{2 \alpha}+20 e^{3 \alpha}+15 e^{4 \alpha}+6 e^{5 \alpha}+e^{6 \alpha}}
$$

The maximum is at the value $\theta=\log 2$, which is demonstrated in the figure below.

The lower and upper confidence bounds are the values of $\theta$ such that $\operatorname{Pr}(M \geq 4 \mid \theta)=0.025$ and $\operatorname{Pr}(M \leq 4 \mid \theta)=0.025$, respectively. These probabilities are plotted in the figure below for $\theta \in[-2,4]$.

> Example 4
This example demonstrates the group() option, which allows the analysis of stratified data. Here the logistic model is

$$
\log \left(\frac{\pi_{i k}}{1-\pi_{i k}}\right)=\theta_{k}+\mathbf{x}_{k i} \boldsymbol{\beta}
$$

where $k$ indexes the $s$ strata, $k=1, \ldots, s$, and $\theta_{k}$ is the strata-specific constant term whose sufficient statistic is $M_{k}=\sum_{i=1}^{n_{k}} Y_{k i}$.

Mehta and Patel (1995) use a case-control study to demonstrate this model, which is useful in comparing the estimates from exlogistic and clogit. This study was intended to determine the role of birth complications in people with schizophrenia (Garsd 1988). Siblings from seven families took part in the study, and each individual was classified as normal or schizophrenic. A birth complication index is recorded for each individual that ranges from 0 , an uncomplicated birth, to 15 , a very complicated birth. Some of the frequencies contained in variable $f$ are greater than 1 , and these count different births at different times where the individual has the same birth complications index, found in variable BCindex.

|  |  |  | max |  |  | 10 |
|  |  |  | Model score |  |  | 6.328033 |
|  |  |  | $\operatorname{Pr}>=$ score |  |  | 0.0167 |
| schizo | Coefficient | Score | Pr $>=$ Score | [95\% conf | . | nterval] |
| BCindex | . 3251178 | 6.328033 | 0.0167 | . 0223423 |  | . 7408832 |

The asymptotic alternative for this model can be estimated using clogit (equivalently, xtlogit, fe) and is listed below for comparison. We must expand the data because clogit will not accept frequency weights if they are not constant within the groups.

```
. expand f
(7 observations created)
. clogit schizo BCindex, group(family) nolog
note: multiple positive outcomes within groups encountered.
Conditional (fixed-effects) logistic regression Number of obs = 29
    LR chi2(1) = 5.20
    Prob > chi2 = 0.0226
    Pseudo R2 = 0.2927
```

| schizo | Coefficient | Std. err. | $z$ | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :---: | :---: | :---: | :---: | :---: |
| BCindex | .3251178 | .1678981 | 1.94 | 0.053 | -.0039565 | .654192 |

Both techniques compute the same regression estimate for the BCindex, which might not be too surprising because both estimation techniques condition on the total number of successes in each group. The difference lies in the $p$-values and confidence intervals. The $p$-value testing $H_{0}: \beta_{\mathrm{BCindex}}=0$ is approximately 0.0167 for the exact conditional scores test and 0.053 for the asymptotic Wald test. Moreover, the exact confidence interval is asymmetric about the estimate and does not contain zero.

## - Technical note

The memory () option limits the amount of memory that exlogistic will consume when computing the conditional distribution of the parameter sufficient statistics. memory () is independent of the data maximum memory setting (see set max_memory in [D] memory), and it is possible for exlogistic to exceed the memory limit specified in set max_memory without terminating. By default, a log is provided that displays the number of enumerations (the size of the conditional distribution)
after processing each observation. Typically, you will see the number of enumerations increase, and then at some point they will decrease as the multivariate shift algorithm (Hirji, Mehta, and Patel 1987) determines that some of the enumerations cannot achieve the observed sufficient statistics of the conditioning variables. When the algorithm is complete, however, it is necessary to store the conditional distribution of the parameter sufficient statistics as a dataset. It is possible, therefore, to get a memory error when the algorithm has completed if there is not enough memory to store the conditional distribution.

## Technical note

Computing the conditional distributions and reported statistics requires data sorting and numerical comparisons. If there is at least one single-precision variable specified in the model, exlogistic will make comparisons with a relative precision of $2^{-5}$. Otherwise, a relative precision of $2^{-11}$ is used. Be careful if you use recast to promote a single-precision variable to double precision (see [D] recast). You might try listing the data in full precision (maybe $\% 20.15 \mathrm{~g}$; see [D] format) to make sure that this is really what you want. See [D] Data types for information on precision of numeric storage types.

## Methods and formulas

Methods and formulas are presented under the following headings:
Sufficient statistics
Conditional distribution and CMLE
MUEs and exact confidence intervals
Conditional hypothesis tests
Sufficient-statistic p-value

## Sufficient statistics

Let $\left\{Y_{1}, Y_{2}, \ldots, Y_{n}\right\}$ be a set of $n$ independent Bernoulli random variables, each of which can realize two outcomes, $\{0,1\}$. For each $i=1, \ldots, n$, we observe $Y_{i}=y_{i}$, and associated with each observation is the covariate row vector of length $p, \mathbf{x}_{i}=\left(x_{i 1}, \ldots, x_{i p}\right)$. Denote $\boldsymbol{\beta}=\left(\beta_{1}, \ldots, \beta_{p}\right)^{T}$ to be the column vector of regression parameters and $\theta$ to be the constant. The sufficient statistic for $\beta_{j}$ is $T_{j}=\sum_{i=1}^{n} Y_{i} x_{i j}, j=1, \ldots, p$, and for $\theta$ is $M=\sum_{i=1}^{n} Y_{i}$. We observe $T_{j}=t_{j}, t_{j}=\sum_{i=1}^{n} y_{i} x_{i j}$, and $M=m, m=\sum_{i=1}^{n} y_{i}$. The probability of observing $\left(Y_{1}=y_{1}, Y_{2}=y_{2}, \ldots, Y_{n}=y_{n}\right)$ is

$$
\operatorname{Pr}\left(Y_{1}=y_{1}, \ldots, Y_{n}=y_{n} \mid \boldsymbol{\beta}, \mathbf{X}\right)=\frac{\exp (m \theta+\mathbf{t} \boldsymbol{\beta})}{\prod_{i=1}^{n}\left\{1+\exp \left(\theta+\mathbf{x}_{i} \boldsymbol{\beta}\right)\right\}}
$$

where $\mathbf{t}=\left(t_{1}, \ldots, t_{p}\right)$ and $\mathbf{X}=\left(\mathbf{x}_{1}^{T}, \ldots, \mathbf{x}_{n}^{T}\right)^{T}$.
The joint distribution of the sufficient statistics $\mathbf{T}$ is obtained by summing over all possible binary sequences $Y_{1}, \ldots, Y_{n}$ such that $\mathbf{T}=\mathbf{t}$ and $M=m$. This probability function is

$$
\operatorname{Pr}\left(T_{1}=t_{1}, \ldots, T_{p}=t_{p}, M=m \mid \boldsymbol{\beta}, \mathbf{X}\right)=\frac{c(\mathbf{t}, m) \exp (m \theta+\mathbf{t} \boldsymbol{\beta})}{\prod_{i=1}^{n}\left\{1+\exp \left(\theta+\mathbf{x}_{i} \boldsymbol{\beta}\right)\right\}}
$$

where $c(\mathbf{t}, m)$ is the combinatorial coefficient of $(\mathbf{t}, m)$ or the number of distinct binary sequences $Y_{1}, \ldots, Y_{n}$ such that $\mathbf{T}=\mathbf{t}$ and $M=m$ (Cox and Snell 1989).

## Conditional distribution and CMLE

Without loss of generality, we will restrict our discussion to computing the CMLE of $\beta_{1}$. If we condition on observing $M=m$ and $T_{2}=t_{2}, \ldots, T_{p}=t_{p}$, the probability function of $\left(T_{1} \mid \beta_{1}, T_{2}=\right.$ $\left.t_{2}, \ldots, T_{p}=t_{p}, M=m\right)$ is

$$
\begin{equation*}
\operatorname{Pr}\left(T_{1}=t_{1} \mid \beta_{1}, T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)=\frac{c(\mathbf{t}, m) e^{t_{1} \beta_{1}}}{\sum_{u} c\left(u, t_{2}, \ldots, t_{p}, m\right) e^{u \beta_{1}}} \tag{1}
\end{equation*}
$$

where the sum in the denominator is over all possible values of $T_{1}$ such that $M=m$ and $T_{2}=t_{2}, \ldots, T_{p}=t_{p}$ and $c\left(u, t_{2}, \ldots, t_{p}, m\right)$ is the combinatorial coefficient of $\left(u, t_{2}, \ldots, t_{p}, m\right)$ (Cox and Snell 1989). The CMLE for $\beta_{1}$ is the value $\widehat{\beta}_{1}$ that maximizes the $\log$ of (1). This optimization task is carried out by ml , using the conditional frequency distribution of $\left(T_{1} \mid T_{2}=t_{2}, \ldots, T_{p}=\right.$ $\left.t_{p}, M=m\right)$ as a dataset. Generating the joint conditional distribution is efficiently computed using the multivariate shift algorithm described by Hirji, Mehta, and Patel (1987).

Difficulties in computing $\widehat{\beta}_{1}$ arise if the observed $\left(T_{1}=t_{1}, \ldots, T_{p}=t_{p}, M=m\right)$ lies on the boundaries of the distribution of $\left(T_{1} \mid T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)$, where the conditional probability function is monotonically increasing (or decreasing) in $\beta_{1}$. Here the CMLE is plus infinity if it is on the upper boundary, $\operatorname{Pr}\left(T_{1} \leq t_{1} \mid T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)=1$, and is minus infinity if it is on the lower boundary of the distribution, $\operatorname{Pr}\left(T_{1} \geq t_{1} \mid T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)=1$. This concept is demonstrated in example 2. When infinite CMLEs occur, the MUE is computed.

## MUEs and exact confidence intervals

The MUE is computed using the technique outlined by Hirji, Tsiatis, and Mehta (1989). First, we find the values of $\beta_{1}^{(u)}$ and $\beta_{1}^{(l)}$ such that

$$
\begin{align*}
& \operatorname{Pr}\left(T_{1} \leq t_{1} \mid \beta_{1}=\beta_{1}^{(u)}, T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)=  \tag{2}\\
& \operatorname{Pr}\left(T_{1} \geq t_{1} \mid \beta_{1}=\beta_{1}^{(l)}, T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)=1 / 2
\end{align*}
$$

The MUE is then $\bar{\beta}_{1}=\left(\beta_{1}^{(l)}+\beta_{1}^{(u)}\right) / 2$. However, if $T_{1}$ is equal to the minimum of the domain of the conditional distribution, $\beta^{(l)}$ does not exist and $\bar{\beta}_{1}=\beta^{(u)}$. If $T_{1}$ is equal to the maximum of the domain of the conditional distribution, $\beta^{(u)}$ does not exist and $\bar{\beta}_{1}=\beta^{(l)}$.

Confidence bounds for $\beta$ are computed similarly, except that we substitute $\alpha / 2$ for $1 / 2$ in (2), where $1-\alpha$ is the confidence level. Here $\beta_{1}^{(l)}$ would then be the lower confidence bound and $\beta_{1}^{(u)}$ would be the upper confidence bound (see example 3).

## Conditional hypothesis tests

To test $H_{0}: \beta_{1}=0$ versus $H_{1}: \beta_{1} \neq 0$, we obtain the exact $p$-value from $\sum_{u \in E} f_{1}(u)-f_{1}\left(t_{1}\right) / 2$ if the mid- $p$-value rule is used and $\sum_{u \in E} f_{1}(u)$ otherwise. Here $E$ is a critical region, and we define $f_{1}(u)=\operatorname{Pr}\left(T_{1}=u \mid \beta_{1}=0, T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)$ for ease of notation. There are two popular ways to define the critical region: the conditional probabilities test and the conditional scores test (Mehta and Patel 1995). The critical region when using the conditional probabilities test is all values of the sufficient statistic for $\beta_{1}$ that have a probability less than or equal to that of the observed $t_{1}, E_{p}=\left\{u: f_{1}(u) \leq f_{1}\left(t_{1}\right)\right\}$. The critical region of the conditional scores test is defined as all values of the sufficient statistic for $\beta_{1}$ such that its score is greater than or equal to that of $t_{1}$,

$$
E_{s}=\left\{u:\left(u-\mu_{1}\right)^{2} / \sigma_{1}^{2} \geq\left(t_{1}-\mu_{1}\right)^{2} / \sigma_{1}^{2}\right\}
$$

Here $\mu_{1}$ and $\sigma_{1}^{2}$ are the mean and variance of $\left(T_{1} \mid \beta_{1}=0, T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)$.

The score statistic is defined as

$$
\left\{\frac{\partial \ell(\beta)}{\partial \beta}\right\}^{2}\left[-E\left\{\frac{\partial^{2} \ell(\beta)}{\partial \beta^{2}}\right\}\right]^{-1}
$$

evaluated at $H_{0}: \beta=0$, where $\ell$ is the log of (1). The score test simplifies to $(t-E[T \mid \beta])^{2} / \operatorname{var}(T \mid \beta)$ (Hirji 2006), where the mean and variance are computed from the conditional distribution of the sufficient statistic with $\beta=0$ and $t$ is the observed sufficient statistic.

## Sufficient-statistic p-value

The $p$-value for testing $H_{0}: \beta_{1}=0$ versus the two-sided alternative when $\left(T_{1}=t_{1} \mid T_{2}=\right.$ $\left.t_{2}, \ldots, T_{p}=t_{p}\right)$ is computed as $2 \times \min \left(p_{l}, p_{u}\right)$, where

$$
\begin{aligned}
p_{l} & =\frac{\sum_{u \leq t_{1}} c\left(u, t_{2}, \ldots, t_{p}, m\right)}{\sum_{u} c\left(u, t_{2}, \ldots, t_{p}, m\right)} \\
p_{u} & =\frac{\sum_{u \geq t_{1}} c\left(u, t_{2}, \ldots, t_{p}, m\right)}{\sum_{u} c\left(u, t_{2}, \ldots, t_{p}, m\right)}
\end{aligned}
$$

It is the probability of observing a more extreme $T_{1}$.

## Title

exlogistic postestimation - Postestimation tools for exlogistic

| Postestimation commands | estat | Remarks and examples |
| :--- | :--- | :--- |
| Reference | Also see |  |

## Postestimation commands

The following postestimation commands are of special interest after exlogistic:

| Command | Description |
| :--- | :--- |
| estat predict | single-observation prediction |
| estat se | report ORs or coefficients and their asymptotic standard errors |

The following standard postestimation commands are also available:
Command Description

```
estat summarize summary statistics for the estimation sample
estimates cataloging estimation results
etable table of estimation results
```

estat summarize is not allowed if the binomial() option was specified in exlogistic.

## estat

## Description for estat

estat predict computes a predicted probability (or linear predictor), its asymptotic standard error, and its exact confidence interval for 1 observation. Predictions are carried out by estimating the constant coefficient after shifting the independent variables and conditioned variables by the values specified in the at () option or by their medians. Therefore, predictions must be done with the estimation sample in memory. If a different dataset is used or if the dataset is modified, then an error will result.
estat se reports odds ratio or coefficients and their asymptotic standard errors. The estimates are stored in the matrix $r$ (estimates).

## Menu for estat

Statistics $>$ Postestimation

## Syntax for estat

Single-observation prediction
estat predict [, pred_options]
Report ORs or coefficients and their asymptotic standard errors

```
estat se [, coef]
```

pred_options
Description
pr probability; the default
$\mathrm{xb} \quad$ linear predictor
at (atspec) use the specified values for the indepvars and condvars()
level(\#)
memory (\#[b|k|m|g])
set confidence level for the predicted value; default is level(95)
set limit on memory usage; default is memory ( 10 m )
[no]log
collect is allowed with estat predict; see [U] 11.1.10 Prefix commands.
These statistics are available only for the estimation sample.

## Options for estat predict

pr , the default, calculates the probability.
xb calculates the linear predictor.
at $($ varname $=\#[[$ varname $=\#][\ldots]])$ specifies values to use in computing the predicted value. Here varname is one of the independent variables, indepvars, or the conditioned variables, condvars(). The default is to use the median of each independent and conditioned variable.
level(\#) specifies the confidence level, as a percentage, for confidence intervals. The default is level (95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.
memory (\# $[\mathrm{b}|\mathrm{k}| \mathrm{m} \mid \mathrm{g}]$ ) sets a limit on the amount of memory estat predict can use when generating the conditional distribution of the constant parameter sufficient statistic. The default is memory ( 10 m ), where m stands for megabyte, or $1,048,576$ bytes. The following are also available: b stands for byte; k stands for kilobyte, which is equal to 1,024 bytes; and g stands for gigabyte, which is equal to 1,024 megabytes. The minimum setting allowed is 1 m and the maximum is 512 m or 0.5 g , but do not attempt to use more memory than is available on your computer. Also see Remarks and examples in [R] exlogistic for details on enumerating the conditional distribution.
log and nolog specify whether to display the enumeration log, which shows the progress of enumerating the distribution of the observed successes conditioned on the independent variables shifted by the values specified in at () (or by their medians). See Methods and formulas in $[R]$ exlogistic for details of the computations. The enumeration log is displayed by default unless you used set iterlog off to suppress it; see set iterlog in [R] set iter.

## Option for estat se

coef requests that the estimated coefficients and their asymptotic standard errors be reported. The default is to report the odds ratios and their asymptotic standard errors.

## Remarks and examples

Predictions must be done using the estimation sample. This is because the prediction is really an estimated constant coefficient (the intercept) after shifting the independent variables and conditioned variables by the values specified in at () or by their medians. The justification for this approach can be seen by rewriting the model as

$$
\log \left(\frac{\pi_{i}}{1-\pi_{i}}\right)=\left(\alpha+\mathbf{x}_{0} \boldsymbol{\beta}\right)+\left(\mathbf{x}_{i}-\mathbf{x}_{0}\right) \boldsymbol{\beta}
$$

where $\mathbf{x}_{0}$ are the specified values for the indepvars (Mehta and Patel 1995). Because the estimation of the constant term is required, this technique is not appropriate for stratified models that used the group() option.

## > Example 1

To demonstrate, we return to the example 2 in $[R]$ exlogistic using data from a prospective study of perinatal infection and HIV-1. Here there was an investigation into whether the blood serum levels of CD4 and CD8 measured in infants at 6 months of age might predict their development of HIV infection. The blood serum levels are coded as ordinal values 0 , 1 , and 2 . These data are used by Mehta and Patel (1995) as an exposition of exact logistic.

```
. use https://www.stata-press.com/data/r18/hiv_n
(Prospective study of perinatal infection of HIV-1; binomial form)
. exlogistic hiv ib2.cd4 ib2.cd8, binomial(n) test(probability)
    (output omitted)
```

Because we did not specify values by using the at () option, the median values of the indepvars are used for the prediction. By default, medians are used instead of means because we want to use values that are observed in the dataset. If the means of the indicators for levels of factor variables ( $0 . \mathrm{cd} 4-1 . \mathrm{cd} 8$ ) were used, we would have created floating point variables in $(0,1)$ that not only do not properly represent the indicator variables but also would be a source of computational inefficiency in generating the conditional distribution. Because the MUE is computed for the predicted value, there is no standard error estimate.

From the example discussions in [R] exlogistic, the infants at highest risk are those with a CD4 level of 0 and a CD8 level of 2 . Below, we use the at () option to make a prediction at these blood serum levels.

```
. estat predict, at(cd4=0 cd8=2) nolog
note: 2b.cd8 is a base level; setting all other levels of cd8 to zero implies
    2b.cd8 = 1.
note: CMLE estimate for _cons is +inf; computing MUE.
Predicted value at 0.cd4 = 1, 1.cd4 = 0, 0.cd8 = 0, 1.cd8 = 0
```

| hiv | Predicted | Std. err. | [95\% conf. interval] |  |
| ---: | ---: | :---: | ---: | ---: |
| Probability | $0.9063 *$ | N/A | 0.4637 | 1.0000 |

(*) identifies median unbiased estimates (MUE) ; because an MUE is computed, there is no SE estimate

## Stored results

estat predict stores the following in $r()$ :
Scalars
$r$ (imue) $\quad 1$ if $r$ (pred) is an MUE and 0 if a CMLE
$r$ (pred) estimated probability or the linear effect
$r(\mathrm{se}) \quad$ asymptotic standard error of $r(p r e d)$
Macros
r (estimate) prediction type: pr or xb
$r$ (level) confidence level
Matrices
$r(\mathrm{ci}) \quad$ confidence interval
$\mathrm{r}(\mathrm{x}) \quad$ indepvars and condvars() values

## Title

expoisson - Exact Poisson regression

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

expoisson fits an exact Poisson regression model, which produces more accurate inference in small samples than standard maximum-likelihood-based Poisson regression. For stratified data, expoisson conditions on the number of events in each stratum and is an alternative to fixed-effects Poisson regression.

## Quick start

Exact Poisson regression of y on $\mathrm{x} 1, \mathrm{x} 2$, and x 3
expoisson y x1 x2 x3
Add exposure variable evar
expoisson y x1 x2 x3, exposure(evar)
Same as above, but condition on values of $x 3$ to save time and memory
expoisson y x1 x2, exposure(evar) condvars(x3)
Same as above, and allow more memory for computing the conditional distribution of sufficient statistics
expoisson y x1 x2, exposure(evar) condvars(x3) memory (100m)
Report incidence-rate ratios rather than coefficients
expoisson y x1 x2 x3, irr
Report conditional scores tests
expoisson y x1 x2 x3, test(score)
Fit a model with strata identified by svar

```
expoisson y x1 x2 x3, group(svar)
```

## Options

[^24]exposure (varname ${ }_{e}$ ), offset (varname ${ }_{o}$ ); see [R] Estimation options.

Options
memory ( $\#[\mathrm{~b}|\mathrm{k}| \mathrm{m} \mid \mathrm{g}]$ ) sets a limit on the amount of memory expoisson can use when computing the conditional distribution of the parameter sufficient statistics. The default is memory ( 25 m ), where m stands for megabyte, or $1,048,576$ bytes. The following are also available: b stands for byte; k stands for kilobyte, which is equal to 1,024 bytes; and g stands for gigabyte, which is equal to 1,024 megabytes. The minimum setting allowed is 1 m and the maximum is 2048 m or 2 g , but do not attempt to use more memory than is available on your computer. Also see the first technical note under example 3 on counting the conditional distribution.
saving (filename [, replace]) saves the joint conditional distribution for each independent variable specified in indepvars. There is one file for each variable, and it is named using the prefix filename with the variable name appended. For example, saving (mydata) with an independent variable named $X$ would generate a data file named mydata_X.dta. Use replace to replace an existing file. Each file contains the conditional distribution for one of the independent variables specified in indepvars conditioned on all other indepvars and those variables specified in condvars(). There are two variables in each data file: the feasible sufficient statistics for the variable's parameter and their associated weights. The weights variable is named $\mathrm{w}_{\mathrm{L}}$.

## Reporting

level(\#); see [R] Estimation options. The level() option will not work on replay because confidence intervals are based on estimator-specific enumerations. To change the confidence level, you must refit the model.
irr reports estimated coefficients transformed to incidence-rate ratios, that is, $\exp (\beta)$ rather than $\beta$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.
test (sufficient |score|probability) reports the $p$-value associated with the observed sufficient statistics, the conditional scores tests, or the conditional probabilities tests, respectively. The default is test (sufficient). All the statistics are computed at estimation time regardless of which is specified. Each statistic may thus also be displayed when replaying results after estimation without having to refit the model; see $[\mathrm{R}]$ expoisson postestimation.
mue ( varlist $_{m}$ ) specifies that median unbiased estimates (MUEs) be reported for the specified variables. By default, the conditional maximum likelihood estimates (CMLEs) are reported, except for those parameters for which the CMLEs are infinite. Specify mue (_all) if you want MUEs for all the indepvars.
midp instructs expoisson to use the mid- $p$-value rule when computing the mUEs, $p$-values, and confidence intervals. This adjustment is for the discreteness of the distribution and halves the value of the discrete probability of the observed statistic before adding it to the $p$-value. The mid- $p$-value rule cannot be applied to MUEs whose corresponding parameter CMLE is infinite.
log and nolog specify whether to display the enumeration log, which shows the progress of computing the conditional distribution of the sufficient statistics. The enumeration $\log$ is displayed by default unless you used set iterlog off to suppress it; see set iterlog in [R] set iter.
display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\% fmt), pformat (\% fmt), and sformat (\% fit); see [R] Estimation options.

Note that the maximum widths for cformat(), pformat(), and sformat() differ from those widths listed in $[\mathrm{R}]$ Estimation options. The maximum width for each format is 9 for expoisson.

The following option is available with expoisson but is not shown in the dialog box: coeflegend; see [R] Estimation options.

## Remarks and examples

Exact Poisson regression estimates the model parameters by using the conditional distributions of the parameters' sufficient statistics, and the resulting parameter estimates are known as CMLEs. Exact Poisson regression is a small-sample alternative to the maximum-likelihood Poisson model. See [R] poisson and [XT] xtpoisson to obtain maximum likelihood estimates (MLEs) for the Poisson model and the fixed-effects Poisson model.

Let $Y_{i}$ denote a Poisson random variable where we observe the outcome $Y_{i}=y_{i}, i=1, \ldots, n$. Associated with each independent observation is a $1 \times p$ vector of covariates, $\mathbf{x}_{i}$. We will denote $\mu_{i}=E\left[Y_{i} \mid \mathbf{x}_{i}\right]$ and use the log-linear model to model the relationship between $Y_{i}$ and $\mathbf{x}_{i}$,

$$
\log \left(\mu_{i}\right)=\theta+\mathbf{x}_{i} \boldsymbol{\beta}
$$

where the constant term, $\theta$, and the $p \times 1$ vector of regression parameters, $\boldsymbol{\beta}$, are unknown. The probability of observing $Y_{i}=y_{i}, i=1, \ldots, n$, is

$$
\operatorname{Pr}(\mathbf{Y}=\mathbf{y})=\prod_{i=1}^{n} \frac{\mu_{i}^{y_{i}} e^{-\mu_{i}}}{y_{i}!}
$$

where $\mathbf{Y}=\left(Y_{1}, \ldots, Y_{n}\right)$ and $\mathbf{y}=\left(y_{1}, \ldots, y_{n}\right)$. The MLEs for $\theta$ and $\boldsymbol{\beta}$ maximize the $\log$ of this function.

The sufficient statistics for $\theta$ and $\beta_{j}, j=1, \ldots, p$, are $M=\sum_{i=1}^{n} Y_{i}$ and $T_{j}=\sum_{i=1}^{n} Y_{i} x_{i j}$, respectively, and we observe $M=m$ and $T_{j}=t_{j}$. expoisson tallies the conditional distribution for each $T_{j}$, given the other sufficient statistics $T_{l}=t_{l}, l \neq j$ and $M=m$. Denote one of these values to be $t_{j}^{(k)}, k=1, \ldots, N$, with weight $w_{k}$ that accounts for all the generated $\mathbf{Y}$ vectors that give rise to $t_{j}^{(k)}$. The conditional probability of observing $T_{j}=t_{j}$ has the form

$$
\begin{equation*}
\operatorname{Pr}\left(T_{j}=t_{j} \mid T_{l}=t_{l}, l \neq j, M=m\right)=\frac{w e^{t_{j} \beta_{j}}}{\sum_{k} w_{k} e^{t_{j}^{(k)} \beta_{j}}} \tag{1}
\end{equation*}
$$

where the sum is over the subset of $\mathbf{T}$ vectors such that $\left(T_{1}^{(k)}=t_{1}, \ldots, T_{j}^{(k)}=t_{j}^{(k)}, \ldots, T_{p}^{(k)}=t_{p}\right)$ and $w$ is the weight associated with the observed $\mathbf{t}$. The CMLE for $\beta_{j}$ maximizes the $\log$ of this function.

Specifying nuisance variables in condvars() prevents expoisson from estimating their associated regression coefficients. These variables are still conditional variables when tallying the conditional distribution for the variables in indepvars.

Inferences from MLEs rely on asymptotics, and if your sample size is small, these inferences may not be valid. On the other hand, inferences from the CMLEs are exact in that they use the conditional distribution of the sufficient statistics outlined above.

For small datasets, the dependent variable can be completely determined by the data. Here the MLEs and the CMLEs are unbounded. When this occurs, expoisson will compute the MUE, the regression estimate that places the observed sufficient statistic at the median of the conditional distribution.

See $[R]$ exlogistic for a more thorough discussion of exact estimation and related statistics.

## $>$ Example 1

Armitage, Berry, and Matthews (2002, 499-501) fit a log-linear model to data containing the number of cerebrovascular accidents experienced by 41 men during a fixed period, each of whom had recovered from a previous cerebrovascular accident and was hypertensive. Sixteen men received treatment, and in the original data, there are three age groups ( $40-49,50-59, \geq 60$ ), but we pool the first two age groups to simplify the example. Armitage, Berry, and Matthews point out that this was not a controlled trial, but the data are useful to inquire whether there is evidence of fewer accidents for the treatment group and if age may be an important factor. The dependent variable count contains the number of accidents, variable treat is an indicator for the treatment group ( $1=$ treatment, $0=$ control), and variable age is an indicator for the age group ( $0=40-59 ; 1=\geq 60$ ).

First, we load the dataset, list it, and tabulate the cerebrovascular accident counts by treatment and age group.

```
. use https://www.stata-press.com/data/r18/cerebacc
(Cerebrovascular accidents in hypotensive-treated and control groups)
. list
```

|  | treat | count | age |
| :--- | ---: | ---: | ---: |
| 1. | Control | 0 | $40 / 59$ |

expoisson generates an enumeration log for each independent variable in indepvars. The conditional distribution of the parameter sufficient statistic is tallied for each independent variable. The conditional distribution for treat, for example, has 30 records containing the weights, $w_{k}$, and feasible sufficient statistics, $t_{\text {treat }}^{(k)}$. In essence, the set of points $\left(w_{k}, t_{\text {treat }}^{(k)}\right), k=1, \ldots, 30$, tallied by expoisson now become the data to estimate the regression coefficient for treat, using (1) as the likelihood. Remember that 1 of the $30\left(w_{k}, t_{\text {treat }}^{(k)}\right)$ must contain the observed sufficient statistic, $t_{\text {treat }}=\sum_{i=1}^{41}$ treat $_{i} \times$ count $_{i}=4$, and its relative position in the sorted set of points (sorted by $t_{\text {treat }}^{(k)}$ ) is how the sufficient-statistic $p$-value is computed. This algorithm is repeated for the age variable.

The regression coefficients for treat and age are numerically identical for both Poisson models. Both models provide evidence that the treatment reduces the rate of cerebrovascular accidents, $\approx e^{-1.59} \approx 0.204$, or a reduction of about $80 \%$. There is no evidence that age plays a role in the rate of accidents.

The results based on the sufficient statistic provide stronger evidence that treatment reduces the rate of cerebrovascular accidents than the corresponding asymptotic statistics. However, the exact confidence intervals are wider than their asymptotic counterparts.

## $>$ Example 2

Agresti $(2013,129)$ used the data from Laird and Olivier (1981) to demonstrate the Poisson model for modeling rates. The data consist of patient survival after heart valve replacement operations. The sample consists of 109 patients that are classified by type of heart valve (aortic, mitral) and by age $(<55, \geq 55)$. Follow-up observations cover lengths from 3 to 97 months, and the time at risk, or exposure, is stored in the variable TAR. The response is whether the subject died. First, we take a look at the data and then estimate the incidence rates (IRs) with expoisson and poisson.

```
. use https://www.stata-press.com/data/r18/heartvalve
(Heart valve replacement data)
. list
\begin{tabular}{|rcrr|}
\hline age & valve & deaths & TAR \\
\hline\(<55\) & Aortic & 4 & 1259 \\
\(<55\) & Mitral & 1 & 2082 \\
\(>=55\) & Aortic & 7 & 1417 \\
\(>=55\) & Mitral & 9 & 1647 \\
\hline
\end{tabular}
```

The age variable is coded 0 for age $<55$ and 1 for age $\geq 55$, and the valve variable is coded 0 for the aortic valve and 1 for the mitral valve. The total number of deaths, $M=21$, is small enough that enumerating the conditional distributions for age and valve type is feasible and asymptotic inferences associated with standard maximum-likelihood Poisson regression may be questionable.
. expoisson deaths i.age i.valve, exposure(TAR) irr

Exact Poisson regression
Number of obs $=4$

| deaths | IRR | Suff. | $2 * \operatorname{Pr}($ Suff. $)$ | [95\% conf. interval] |  |
| :---: | ---: | :---: | ---: | ---: | ---: |
| age <br> $>=55$ <br> valve <br> Mitral <br> $\ln (T A R)$ | 3.390401 | 16 | 0.0194 | 1.182297 | 11.86935 |

| Poisson regression | Number of obs | $=\quad 4$ |
| :---: | :---: | :---: |
|  | LR chi2(2) | $=7.62$ |
|  | Prob > chi2 | $=0.0222$ |
| Log likelihood = -8.1747285 | Pseudo R2 | $=0.3178$ |

| deaths | IRR | Std. err. | z | P>\|z| | [95\% conf. interval] |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| age <br> $>=55$ | 3.390401 | 1.741967 | 2.38 | 0.017 | 1.238537 | 9.280965 |
| valve |  |  |  |  |  |  |
| Mitral |  |  |  |  |  |  |
| _cons |  |  |  |  |  |  |
| ln(TAR) | .7190197 | .3150492 | -0.75 | 0.452 | .3046311 | 1.6971 |

Note: _cons estimates baseline incidence rate.
The CMLE and the MLE are numerically identical. We have strong evidence that the death rate for the older age group is higher than the younger age group, specifically 3.4 times higher ( $p=0.017$ ). This means that for every death in the younger group each month, we would expect about three deaths in the older group. The IR estimate for valve type is approximately 0.72 , but we do not have enough evidence to claim that it is different from one. The exact Poisson confidence intervals are a bit wider than the asymptotic confidence intervals.

You can use ir (see [R] Epitab) to estimate IRs and exact confidence intervals for one covariate, and we compare these confidence intervals with those from expoisson, where we estimate the IR by using age only.

Exact Poisson regression
Number of obs $=4$

| deaths | IRR | Suff. | $2 * \operatorname{Pr}($ Suff. $)$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| age | 3.489295 | 16 | 0.0099 | 1.324926 | 10.64922 |
| $\ln (T A R)$ | 1 | (exposure) |  |  |  |

Note: Mid-p-value computed for the probabilities and CIs.
Both ir and expoisson give identical IRs and $p$-values. Both report the two-sided exact $p$-value by using the mid- $p$-value rule that accounts for the discreteness in the distribution by subtracting $p_{1 / 2}=$ $\operatorname{Pr}(T=t) / 2$ from $p_{l}=\operatorname{Pr}(T \leq t)$ and $p_{g}=\operatorname{Pr}(T \geq t)$, computing $2 \times \min \left(p_{l}-p_{1 / 2}, p_{g}-p_{1 / 2}\right)$. By default, expoisson will not use the mid- $p$-value rule (when you exclude the midp option), and here the two-sided exact $p$-value would be $2 \times \min \left(p_{l}, p_{g}\right)=0.0158$. The confidence intervals differ because expoisson uses the mid- $p$-value rule when computing the confidence intervals, yet ir does not. You can verify this by executing expoisson without the midp option for this example; you will get the same confidence intervals as ir.

You can replay expoisson to view the conditional scores test or the conditional probabilities test by using the test() option.

| Exact Poisson regression |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

| $\ln (\mathrm{TAR})$ |  | (exposure) |  |  |  |

[^25]All the statistics for expoisson are defined in Methods and formulas of [R] exlogistic. Apart from enumerating the conditional distributions for the logistic and Poisson sufficient statistics, computationally, the primary difference between exlogistic and expoisson is the weighting values in the likelihood for the parameter sufficient statistics.

## > Example 3

In this example, we fabricate data that will demonstrate the difference between the CMLE and the MUE when the CMLE is not infinite. A difference in these estimates will be more pronounced when the probability of the coefficient sufficient statistic is skewed when plotted as a function of the regression coefficient.

(*) median unbiased estimates (MUE)
We observe $\left(x_{i}, y_{i}\right), i=1, \ldots, 9$. If we condition on $m=\sum_{i=1}^{9} y_{i}=12$, the conditional distribution of $T_{x}=\sum_{i} Y_{i} x_{i}$ has a size of 5,479 elements. For each entry in this enumeration, a realization of $Y_{i}=y_{i}^{(k)}, k=1, \ldots, 5,479$, is generated such that $\sum_{i} y_{i}^{(k)}=12$. One of these realizations produces the observed $t_{x}=\sum_{i} y_{i} x_{i} \approx 1.5234$.

Below is a graphical display comparing the CMLE with the MUE. We plot $\operatorname{Pr}\left(T_{x}=t_{x} \mid M=12, \beta_{x}\right)$ versus $\beta_{x},-6 \leq \beta_{x} \leq 1$, in the upper panel and the cumulative probabilities, $\operatorname{Pr}\left(T_{x} \leq t_{x} \mid M=\right.$ $\left.12, \beta_{x}\right)$ and $\operatorname{Pr}\left(T_{x} \geq t_{x} \mid M=12, \beta_{x}\right)$, in the lower panel.

The location of the CMLE, indicated by the dashed line, is at the mode of the probability profile, and the MUE, indicated by the dotted line, is to the right of the mode. If we solve for the $\beta_{x}^{(u)}$ and $\beta_{x}^{(l)}$ such that $\operatorname{Pr}\left(T_{x} \leq t_{x} \mid M=12, \beta_{x}^{(u)}\right)=1 / 2$ and $\operatorname{Pr}\left(T_{x} \geq t_{x} \mid M=12, \beta_{x}^{(l)}\right)=1 / 2$, the MUE is $\left(\beta_{x}^{(u)}+\beta_{x}^{(l)}\right) / 2$. As you can see in the lower panel, the MUE cuts through the intersection of these cumulative probability profiles.

## - Technical note

The memory () option limits the amount of memory that expoisson will consume when computing the conditional distribution of the parameter sufficient statistics. memory () is independent of the data maximum memory setting (see set max_memory in [D] memory), and it is possible for expoisson to exceed the memory limit specified in set max_memory without terminating. By default, a log is provided that displays the number of enumerations (the size of the conditional distribution) after processing each observation. Typically, you will see the number of enumerations increase, and then at some point they will decrease as the multivariate shift algorithm (Hirji, Mehta, and Patel 1987) determines that some of the enumerations cannot achieve the observed sufficient statistics of the conditioning variables. When the algorithm is complete, however, it is necessary to store the conditional distribution of the parameter sufficient statistics as a dataset. It is possible, therefore, to get a memory error when the algorithm has completed if there is not enough memory to store the conditional distribution.

## - Technical note

Computing the conditional distributions and reported statistics requires data sorting and numerical comparisons. If there is at least one single-precision variable specified in the model, expoisson will make comparisons with a relative precision of $2^{-5}$. Otherwise, a relative precision of $2^{-11}$ is used. Be careful if you use recast to promote a single-precision variable to double precision (see [D] recast). You might try listing the data in full precision (maybe $\% 20.15 \mathrm{~g}$; see [D] format) to make sure that this is really what you want. See [D] Data types for information on precision of numeric storage types.

## Methods and formulas

Let $\left\{Y_{1}, Y_{2}, \ldots, Y_{n}\right\}$ be a set of $n$ independent Poisson random variables. For each $i=1, \ldots, n$, we observe $Y_{i}=y_{i} \geq 0$, and associated with each observation is the covariate row vector of length $p, \mathbf{x}_{i}=\left(x_{i 1}, \ldots, x_{i p}\right)$. Denote $\boldsymbol{\beta}=\left(\beta_{1}, \ldots, \beta_{p}\right)^{T}$ to be the column vector of regression parameters and $\theta$ to be the constant. The sufficient statistic for $\beta_{j}$ is $T_{j}=\sum_{i=1}^{n} Y_{i} x_{i j}, j=1, \ldots, p$, and for $\theta$ is $M=\sum_{i=1}^{n} Y_{i}$. We observe $T_{j}=t_{j}, t_{j}=\sum_{i=1}^{n} y_{i} x_{i j}$, and $M=m, m=\sum_{i=1}^{n} y_{i}$. Let $\kappa_{i}$ be the exposure for the $i$ th observation. Then the probability of observing $\left(Y_{1}=y_{1}, Y_{2}=y_{2}, \ldots, Y_{n}=y_{n}\right)$ is

$$
\operatorname{Pr}\left(Y_{1}=y_{1}, \ldots, Y_{n}=y_{n} \mid \boldsymbol{\beta}, \mathbf{X}, \boldsymbol{\kappa}\right)=\frac{\exp (m \theta+\mathbf{t} \boldsymbol{\beta})}{\exp \left\{\sum_{i=1}^{n} \kappa_{i} \exp \left(\theta+\mathbf{x}_{i} \boldsymbol{\beta}\right)\right\}} \prod_{i=1}^{n} \frac{\kappa_{i}^{y_{i}}}{y_{i}!}
$$

where $\mathbf{t}=\left(t_{1}, \ldots, t_{p}\right), \mathbf{X}=\left(\mathbf{x}_{1}^{T}, \ldots, \mathbf{x}_{n}^{T}\right)^{T}$, and $\kappa=\left(\kappa_{1}, \ldots, \kappa_{n}\right)^{T}$.
The joint distribution of the sufficient statistics $(\mathbf{T}, M)$ is obtained by summing over all possible sequences $Y_{1} \geq 0, \ldots, Y_{n} \geq 0$ such that $\mathbf{T}=\mathbf{t}$ and $M=m$. This probability function is

$$
\operatorname{Pr}\left(T_{1}=t_{1}, \ldots, T_{p}=t_{p}, M=m \mid \boldsymbol{\beta}, \mathbf{X}, \boldsymbol{\kappa}\right)=\frac{\exp (m \theta+\mathbf{t} \boldsymbol{\beta})}{\exp \left\{\sum_{i=1}^{n} \kappa_{i} \exp \left(\theta+\mathbf{x}_{i} \boldsymbol{\beta}\right)\right\}}\left(\sum_{\mathbf{u}} \prod_{i=1}^{n} \frac{\kappa_{i}^{u_{i}}}{u_{i}!}\right)
$$

where the sum $\sum_{\mathbf{u}}$ is over all nonnegative vectors $\mathbf{u}$ of length $n$ such that $\sum_{i=1}^{n} u_{i}=m$ and $\sum_{i=1}^{n} u_{i} \mathbf{x}_{i}=\mathbf{t}$.

## Conditional distribution

Without loss of generality, we will restrict our discussion to the conditional distribution of the sufficient statistic for $\beta_{1}, T_{1}$. If we condition on observing $M=m$ and $T_{2}=t_{2}, \ldots, T_{p}=t_{p}$, the probability function of ( $\left.T_{1} \mid \beta_{1}, T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)$ is

$$
\begin{equation*}
\operatorname{Pr}\left(T_{1}=t_{1} \mid \beta_{1}, T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)=\frac{\left(\sum_{\mathbf{u}} \prod_{i=1}^{n} \frac{\kappa_{i}^{u_{i}}}{u_{i}!}\right) e^{t_{1} \beta_{1}}}{\sum_{\mathbf{v}}\left(\prod_{i=1}^{n} \frac{\kappa_{i}^{v_{i}}}{v_{i}!}\right) e^{\beta_{1} \sum_{i} v_{i} x_{i 1}}} \tag{2}
\end{equation*}
$$

where the sum $\sum_{\mathbf{u}}$ is over all nonnegative vectors $\mathbf{u}$ of length $n$ such that $\sum_{i=1}^{n} u_{i}=m$ and $\sum_{i=1}^{n} u_{i} \mathbf{x}_{i}=\mathbf{t}$, and the sum $\sum_{\mathbf{v}}$ is over all nonnegative vectors $\mathbf{v}$ of length $n$ such that $\sum_{i=1}^{n} v_{i}=m$, $\sum_{i=1}^{n=1} v_{i} x_{i 2}=t_{2}, \ldots, \sum_{i=1}^{n} v_{i} x_{i p}=t_{p}$. The CMLE for $\beta_{1}$ is the value that maximizes the log of (1). This optimization task is carried out by ml (see [R] ml ), using the conditional distribution of $\left(T_{1} \mid T_{2}=t_{2}, \ldots, T_{p}=t_{p}, M=m\right)$ as a dataset. This dataset consists of the feasible values and weights for $T_{1}$,

$$
\left\{\left(s_{1}, \prod_{i=1}^{n} \frac{\kappa_{i}^{v_{i}}}{v_{i}!}\right): \sum_{i=1}^{n} v_{i}=m, \sum_{i=1}^{n} v_{i} x_{i 1}=s_{1}, \sum_{i=1}^{n} v_{i} x_{i 2}=t_{2}, \ldots, \sum_{i=1}^{n} v_{i} x_{i p}=t_{p}\right\}
$$

Computing the CMLE, MUE, confidence intervals, conditional hypothesis tests, and sufficient statistic $p$-values is discussed in Methods and formulas of [R] exlogistic. The only difference between the two techniques is the use of the weights; that is, the weights for exact logistic are the combinatorial coefficients, $c(\mathbf{t}, m)$, in (1) of Methods and formulas in [R] exlogistic. expoisson and exlogistic use the same ml likelihood evaluator to compute the CMLEs as well as the same ado-programs and Mata functions to compute the MUEs and estimate statistics.

expoisson postestimation - Postestimation tools for expoisson

Postestimation commands estat Remarks and examples Also see

## Postestimation commands

The following postestimation command is of special interest after expoisson:

| Command | Description |
| :--- | :--- |
| estat se | report coefficients or IRRs and their asymptotic standard errors |

The following standard postestimation commands are also available:
Command
Description
estat summarize
summary statistics for the estimation sample
estimates
cataloging estimation results
etable
table of estimation results

## estat

## Description for estat

estat se reports regression coefficients or incidence-rate asymptotic standard errors. The estimates are stored in the matrix $r$ (estimates).

## Menu for estat

Statistics $>$ Postestimation

## Syntax for estat

```
estat se [, irr]
```

## Option for estat

irr requests that the incidence-rate ratios and their asymptotic standard errors be reported. The default is to report the coefficients and their asymptotic standard errors.

## Remarks and examples

## Example 1

To demonstrate estat se after expoisson, we use the British physicians smoking data.

```
. use https://www.stata-press.com/data/r18/smokes
(Cigarette smoking and lung cancer among British physicians (45-49 years))
. expoisson cases smokes, exposure(peryrs) irr nolog

## Description

fp <term>: est_cmd fits models with the "best"-fitting fractional polynomial substituted for <term> wherever it appears in est_cmd. fp <weight>: regress mpg <weight> foreign would fit a regression model of mpg on a fractional polynomial in weight and (linear) foreign.

By specifying option $f p()$, you may set the exact powers to be used. Otherwise, a search through all possible fractional polynomials up to the degree set by dimension() with the powers set by powers() is performed.
fp without arguments redisplays the previous estimation results, just as typing est_cmd would. You can type either one. fp will include a fractional polynomial comparison table.
fp generate creates fractional polynomial power variables for a given set of powers. For instance, $f p$ <weight>: regress mpg <weight> foreign might produce the fractional polynomial weight $^{(-2,-1)}$ and store weight ${ }^{-2}$ in weight_1 and weight ${ }^{-1}$ in weight_2. Typing fp generate weight^ $(-2-1)$ would allow you to create the same variables in another dataset.

See [R] mfp for multivariable fractional polynomial models.

## Quick start

Fit models with fractional polynomials
Find optimal second-degree fractional polynomial of $x 1$ in regression of $y$ on $x 2$ and $x 3$
fp <x1>: regress y <x1> x2 x3
Same as above, but search only powers of $-1,-0.5,1$, and 2 .
fp <x1>, power (-1 -. 5 1 2) : regress y <x1> x2 x3
Same as above, but allow search to include third-degree fractional polynomials
fp <x1>, power(-1-. 5 1 2) dimension(3): regress y <x1> x2 x3
Fit model including $\mathrm{x} 1^{-2}$ and $\mathrm{x} 1^{2}$ without performing search
fp <x1>, fp(-2 2): regress y <x1> x2 x3
Rescale x 1 to nonextreme positive values when computing fractional polynomials
fp <x1>, scale: regress y <x1> x2 x3
Same as above, and center fractional polynomial of $x 1$ at its scaled mean
fp <x1>, center scale: regress y <x1> x2 x3
Set fractional polynomial to zero for nonpositive values of $x 1$
fp <x1>, zero: regress y <x1> x2 x3
Same as above, and include an indicator variable in the model for nonpositive values of x 1
fp <x1>, catzero: regress y <x1> x2 x3

Create variables corresponding to fractional polynomial powers
Generate $\mathrm{x} 1 \_1$ and $\mathrm{x} 1 \_2$ corresponding to $\mathrm{x} 1^{-2}$ and $\mathrm{x} 1^{2}$
fp generate $\mathrm{x} 1^{\wedge}\left(\begin{array}{ll}-2 & 2\end{array}\right)$
Same as above, but generate fractional polynomial variables with automatic scaling and centering
fp generate $\mathrm{x} 1^{\wedge}(-22)$, center scale

Note: In the above examples, regress could be replaced with any estimation command allowing the fp prefix.

## fp generate

Statistics $>$ Linear models and related $>$ Fractional polynomials $>$ Create fractional polynomial variables

## Syntax

## Estimation

```
fp <term> [, est_options]: est_cmd
```

Specify that fractional powers of varname be calculated during estimation
fp <term>(varname) [, est_options]: est_cmd

Replay estimation results
fp [, replay_options]

Create specified fractional polynomial power variables fp generate [type][newvar =] varname^(numlist) [if] [in] [, gen_options]
est_cmd may be almost any estimation command that stores the e(ll) result. To confirm whether fp works with a specific est_cmd, see the documentation for that est_cmd. est_cmd may not contain other prefix commands; see [U] 11.1.10 Prefix commands.
Instances of <term> (with the angle brackets) that occur within est_cmd are replaced in est_cmd by a varlist containing the fractional powers of the variable term. These variables will be named term_1, term_2, ....
fp performs est_cmd with this substitution, fitting a fractional polynomial regression in term.

Main
powers (\# \# ... \#) powers to be searched; default is powers ( $-2-1-.50 .5123$ ) dimension(\#) maximum degree of fractional polynomial; default is dimension(2)

## Options

Options are presented under the following headings:
Options for $f p$
Options for fp generate

## Options for fp

$\qquad$ Main
powers (\# \# ... \#) specifies that a search be performed and details about the search provided. powers() works with the dimension() option; see below. The default is powers ( $-2-1-.50$ .5123 ).
dimension(\#) specifies the maximum degree of the fractional polynomial to be searched. The default is dimension(2).

If the defaults for both powers() and dimension() are used, then the fractional polynomial could be any of the following 44 possibilities:

$$
\begin{gathered}
\text { term }^{(-2)} \\
\text { term }^{(-1)} \\
\vdots \\
\text { term }^{(3)} \\
\text { term }^{(-2)}, \text { term }^{(-2)} \\
\text { term }^{(-2)}, \text { term }^{(-1)} \\
\vdots \\
\text { term }^{(-2)}, \text { term }^{(3)} \\
\text { term }^{(-1)}, \text { term }^{(-2)} \\
\vdots \\
\text { term }^{(3)}, \text { term }^{(3)}
\end{gathered}
$$

fp(\# \# ... \#) specifies that no search be performed and that the fractional polynomial specified be used. fp() is an alternative to powers() and dimension().

## Options

classic performs automatic scaling and centering and omits the comparison table. Specifying classic is equivalent to specifying scale, center, and nocompare.
replace replaces existing fractional polynomial power variables named term_1, term_2, ....
all specifies that term_1, term_2, .. be filled in for all observations in the dataset rather than just for those in e(sample).
scale (\#_a \#_b) specifies that term be scaled in the way specified, namely, that $($ term $+a) / b$ be calculated. All values of the scaled term are required to be greater than zero unless you specify options zero or catzero. Values should not be too large or too close to zero, because by default, cubic powers and squared reciprocal powers will be considered. When scale $(a b)$ is specified, values in the variable term are not modified; fp merely remembers to scale the values whenever powers are calculated.

You will probably not use scale $(a b)$ for values of $a$ and $b$ that you create yourself, although you could. It is usually easier just to generate a scaled variable. For instance, if term is age, and age in your data is required to be greater than or equal to 20 , you might generate an age 5 variable, for use as term:

```
. generate age5 = (age-19)/5
```

scale ( $a b$ ) is useful when you previously fit a model using automatic scaling (option scale) in one dataset and now want to create the fractional polynomials in another. In the first dataset, fp with scale added notes to the dataset concerning the values of $a$ and $b$. You can see them by typing

```
. notes
```

You can then use fp generate, scale ( $a b$ ) in the second dataset.
The default is to use term as it is used in calculating fractional powers; thus, term's values are required to be greater than zero unless you specify options zero or catzero. Values should not be too large, because by default, cubic powers will be considered.
scale specifies that term be scaled to be greater than zero and not too large in calculating fractional powers. See Scaling for more details. When scale is specified, values in the variable term are not modified; fp merely remembers to scale the values whenever powers are calculated.
center (\#_c) reports results for the fractional polynomial in (scaled) term, centered on $c$. The default is to perform no centering.
term $^{\left(p_{1}, p_{2}, \ldots, p_{m}\right)}-c^{\left(p_{1}, p_{2}, \ldots, p_{m}\right)}$ is reported. This makes the constant coefficient (intercept) easier to interpret. See Centering for more details.
center performs center $(c)$, where $c$ is the mean of (scaled) term.
zero and catzero specify how nonpositive values of term are to be handled. By default, nonpositive values of term are not allowed, because we will be calculating natural logarithms and fractional powers of term. Thus, an error message is issued.
zero sets the fractional polynomial value to zero for nonpositive values of (scaled) term.
catzero sets the fractional polynomial value to zero for nonpositive values of (scaled) term and includes a dummy variable indicating where nonpositive values of (scaled) term appear in the model.

## Reporting

nocompare suppresses display of the comparison tests.
reporting_options are any options allowed by est_cmd for replaying estimation results.

## Options for $\mathfrak{f p}$ generate

Main
replace replaces existing fractional polynomial power variables named term_1, term_2, ...
scale(\#_a \#_b) specifies that term be scaled in the way specified, namely, that (term+a) $/ b$ be calculated. All values of the scaled term are required to be greater than zero unless you specify options zero or catzero. Values should not be too large or too close to zero, because by default, cubic powers and squared reciprocal powers will be considered. When scale ( $a b$ ) is specified, values in the variable term are not modified; fp merely remembers to scale the values whenever powers are calculated.

You will probably not use scale $(a b)$ for values of $a$ and $b$ that you create yourself, although you could. It is usually easier just to generate a scaled variable. For instance, if term is age, and age in your data is required to be greater than or equal to 20 , you might generate an age 5 variable, for use as term:

```
. generate age5 = (age-19)/5
```

scale ( $a b$ ) is useful when you previously fit a model using automatic scaling (option scale) in one dataset and now want to create the fractional polynomials in another. In the first dataset, fp with scale added notes to the dataset concerning the values of $a$ and $b$. You can see them by typing

```
. notes
```

You can then use fp generate, $\operatorname{scale}(a b)$ in the second dataset.
The default is to use term as it is used in calculating fractional powers; thus, term's values are required to be greater than zero unless you specify options zero or catzero. Values should not be too large, because by default, cubic powers will be considered.
scale specifies that term be scaled to be greater than zero and not too large in calculating fractional powers. See Scaling for more details. When scale is specified, values in the variable term are not modified; fp merely remembers to scale the values whenever powers are calculated.
center (\#_c) reports results for the fractional polynomial in (scaled) term, centered on $c$. The default is to perform no centering.
term ${ }^{\left(p_{1}, p_{2}, \ldots, p_{m}\right)}-c^{\left(p_{1}, p_{2}, \ldots, p_{m}\right)}$ is reported. This makes the constant coefficient (intercept) easier to interpret. See Centering for more details.
center performs center $(c)$, where $c$ is the mean of (scaled) term.
zero and catzero specify how nonpositive values of term are to be handled. By default, nonpositive values of term are not allowed, because we will be calculating natural logarithms and fractional powers of term. Thus, an error message is issued.
zero sets the fractional polynomial value to zero for nonpositive values of (scaled) term.
catzero sets the fractional polynomial value to zero for nonpositive values of (scaled) term and includes a dummy variable indicating where nonpositive values of (scaled) term appear in the model.

## Remarks and examples

Remarks are presented under the following headings:
Fractional polynomial regression
Scaling
Centering
Examples

## Fractional polynomial regression

Regression models based on fractional polynomial functions of a continuous covariate are described by Royston and Altman (1994).

Fractional polynomials increase the flexibility afforded by the family of conventional polynomial models. Although polynomials are popular in data analysis, linear and quadratic functions are limited in their range of curve shapes, whereas cubic and higher-order curves often produce undesirable artifacts such as edge effects and waves.

Fractional polynomials differ from regular polynomials in that 1) they allow logarithms, 2) they allow noninteger powers, and 3) they allow powers to be repeated.

We will write a fractional polynomial in $x$ as

$$
x^{\left(p_{1}, p_{2}, \ldots, p_{m}\right)^{\prime}} \boldsymbol{\beta}
$$

We will write $x^{(p)}$ to mean a regular power except that $x^{(0)}$ is to be interpreted as meaning $\ln (x)$ rather than $x^{(0)}=1$.

Then if there are no repeated powers in $\left(p_{1}, p_{2}, \ldots, p_{m}\right)$,

$$
x^{\left(p_{1}, p_{2}, \ldots, p_{m}\right) \prime} \boldsymbol{\beta}=\beta_{0}+\beta_{1} x^{\left(p_{1}\right)}+\beta_{2} x^{\left(p_{2}\right)}+\cdots+\beta_{m} x^{\left(p_{m}\right)}
$$

Powers are allowed to repeat in fractional polynomials. Each time a power repeats, it is multiplied by another $\ln (x)$. As an extreme case, consider the fractional polynomial with all-repeated powers, say, $m$ of them,

$$
x^{(p, p, \ldots, p) \prime} \boldsymbol{\beta}=\beta_{0}+\beta_{1} x^{(p)}+\beta_{2} x^{(p)} \ln (x)+\cdots+\beta_{m} x^{(p)}\{\ln (x)\}^{m-1}
$$

Thus, the fractional polynomial $x^{(0,0,2) \prime} \boldsymbol{\beta}$ would be

$$
\begin{aligned}
x^{(0,0,2) \prime} \boldsymbol{\beta} & =\beta_{0}+\beta_{1} x^{(0)}+\beta_{2} x^{(0)} \ln (x)+\beta_{3} x^{(2)} \\
& =\beta_{0}+\beta_{1} \ln (x)+\beta_{2}\{\ln (x)\}^{2}+\beta_{3} x^{2}
\end{aligned}
$$

With this definition, we can obtain a much wider range of shapes than can be obtained with regular polynomials. The following graphs appeared in Royston and Sauerbrei (2008, sec. 4.5). The first graph shows the shapes of differing fractional polynomials.

The second graph shows some of the curve shapes available with different $\boldsymbol{\beta}$ s for the degree-2 fractional polynomial, $x^{(-2,2)}$.

In modeling a fractional polynomial, Royston and Sauerbrei (2008) recommend choosing powers from among $\{-2,-1,-0.5,0,0.5,1,2,3\}$. By default, fp chooses powers from this set, but other powers can be explicitly specified in the powers () option.
fp <term> : est_cmd fits models with the terms of the best-fitting fractional polynomial substituted for <term> wherever it appears in est_cmd. We will demonstrate with auto.dta, which contains repair records and other information about a variety of vehicles in 1978.

We use $f p$ to find the best fractional polynomial in automobile weight (lbs.) (weight) for the linear regression of miles per gallon ( mpg ) on weight and an indicator of whether the vehicle is foreign (foreign).

By default, fp will fit degree-2 fractional polynomial (FP2) models and choose the fractional powers from the set $\{-2,-1,-0.5,0,0.5,1,2,3\}$. Because car weight is measured in pounds and will have a cubic transformation applied to it, we shrink it to a smaller scale before estimation by dividing by 1,000 .

We modify the existing weight variable for conciseness and to facilitate the comparison of tables. When applying a data transformation in practice, rather than modifying the existing variables, you should create new variables that hold the transformed values.

fp begins by showing the model-comparison table. This table shows the best fractional polynomial model of weight for each examined degree, $m$, which is obtained by searching through all possible power combinations. The row labeled omitted describes the null model, which entirely omits weight from the model. A separate row is provided for the model with a linear function of weight because it is often the default when including a predictor in the model.

The fractional powers of the models are shown in the Powers column. An estimate of the residual standard error is given in the Residual std. dev. column. The model deviance, which we define as twice the negative log likelihood, is given in the Deviance column. The Deviance diff. column reports the difference in deviance compared with the model with the lowest deviance, which is always the model with the highest-degree fractional polynomial.

The Test df column displays the degrees of freedom used when testing a model's fit against the fit of the model with the lowest deviance. For normal error models such as linear regression, a partial $F$ test is performed, and Test df is the numerator degrees of freedom of the $F$ test. In other settings, a likelihood-ratio test is performed, and Test df is the degrees of freedom of the $\chi^{2}$ statistic. In both cases, the $p$-value for the test is reported in column $P$.

Under robust variance estimation and some other cases (see [R] Irtest), the likelihood-ratio test cannot be performed. When the likelihood-ratio test cannot be performed on the model specified in est_cmd, fp still reports the model-comparison table, but the comparison tests are not performed.
fp reports the "best" model as the model with the lowest deviance; however, users may choose a more efficient model based on the comparison table. They may choose the lowest degree model that the partial $F$ test (or likelihood-ratio test) fails to reject in favor of the lowest deviance model.

After the comparison table, the results of the estimation command for the lowest deviance model are shown. Here the best model has terms weight ${ }^{(-2,-2)}$. However, based on the model-comparison table, we can reject the model without weight and the linear model at the 0.1 significance level. We fail to reject the $m=1$ model at any reasonable level. We will choose the FP1 model, which includes weight ${ }^{(-.5)}$.

We use $f p$ again to estimate the parameters for this model. We use the $f p()$ option to specify what powers we want to use; this option specifies that we do not want to perform a search for the best powers. We also specify the replace option to overwrite the previously created fractional polynomial power variables.

```
. fp <weight>, fp(-.5) replace: regress mpg <weight> foreign
-> regress mpg weight_1 foreign
```

## Scaling

Fractional polynomials are defined only for positive term variables. By default, fp will assume that the variable $x$ is positive and attempt to compute fractional powers of $x$. If the positive value assumption is incorrect, an error will be reported and estimation will not be performed.

If the values of the variable are too large or too small, the reported results of $f p$ may be difficult to interpret. By default, cubic powers and squared reciprocal powers will be considered in the search for the best fractional polynomial in term.

We can scale the variable $x$ to 1) make it positive and 2) ensure its magnitude is not too large or too small.

Suppose you have data on hospital patients with age as a fractional polynomial variable of interest. age is required to be greater than or equal to 20 , so you might generate an age 5 variable by typing

```
. generate age5 = (age-19)/5
```

A unit change in age5 is equivalent to a five-year change in age, and the minimum value of age 5 is $1 / 5$ instead of 20 .

In the automobile example of Fractional polynomial regression, our term variable was automobile weight (lbs.). Cars weigh in the thousands of pounds, so cubing their weight figures results in large numbers. We prevented this from being a problem by shrinking the weight by 1,000 ; that is, we typed

```
. replace weight = weight/1000
```

Calendar year is another type of variable that can have a problematically large magnitude. We can shrink this by dividing by 10 , making a unit change correspond to a decade.

```
. generate decade = calendar_year/10
```

You may also have a variable that measures deviation from zero. Perhaps x has already been demeaned and is symmetrically about zero. The fractional polynomial in $x$ will be undefined for half of its domain. We can shift the location of $x$, making it positive by subtracting its minimum and adding a small number to it. Suppose $x$ ranges from -4 to 4 ; we could use
. generate newx $=x+5$
Rescaling ourselves provides easily communicated results. We can tell exactly how the scaling was performed and how it should be performed in similar applications.

Alternatively, fp can scale the fractional polynomial variable so that its values are positive and the magnitude of the values are not too large. This can be done automatically or by directly specifying the scaling values.

Scaling can be automatically performed with $f p$ by specifying the scale option. If term has nonpositive values, the minimum value of term is subtracted from each observation of term. In this case, the counting interval, the minimum distance between the sorted values of term, is also added to each observation of term.

After adjusting the location of term so that its minimum value is positive, creating term*, automatic scaling will divide each observation of term by a power of ten. The exponent of this scaling factor is given by

$$
\begin{aligned}
p & =\log _{10}\left\{\max \left(\text { term }^{*}\right)-\min \left(\text { term }^{*}\right)\right\} \\
p^{*} & =\operatorname{sign}(p) \text { floor }(|p|)
\end{aligned}
$$

Rather than letting fp automatically choose the scaling of term, you may specify adjustment and scale factors $a$ and $b$ by using the scale $(a b)$ option. Fractional powers are then calculated using the $($ term $+a) / b$ values.

When scale or scale $(a b)$ is specified, values in the variable term are not modified; fp merely remembers to scale the values whenever powers are calculated.

In addition to fp , both scale and scale $(a b)$ may be used with fp generate.
You will probably not use scale $(a b)$ with fp for values of $a$ and $b$ that you create yourself, although you could. As we demonstrated earlier, it is usually easier just to generate a scaled variable.
scale ( $a b$ ) is useful when you previously fit a model using scale in one dataset and now want to create the fractional polynomials in another. In the first dataset, fp with scale added notes to the dataset concerning the values of $a$ and $b$. You can see them by typing

```
. notes
```

You can then use fp generate, scale ( $a b$ ) in the second dataset.
When you apply the scaling rules of a previously fit model to new data with the scale ( $a b$ ) option, it is possible that the scaled term may have nonpositive values. $f p$ will be unable to calculate the fractional powers of the term in this case and will issue an error.

The options zero and catzero cause $f p$ and $f p$ generate to output zero values for each fractional polynomial variable when the input (scaled) fractional polynomial variable is nonpositive. Specifying catzero causes a dummy variable indicating nonpositive values of the (scaled) fractional polynomial variable to be included in the model. A detailed example of the use of catzero and zero is shown in example 3 below.

Using the scaling options, we can fit our previous model again using the auto.dta. We specify scale (01000) so that $f p$ will shrink the magnitude of weight in estimating the regression. This is done for demonstration purposes because our scaling rule is simple. As mentioned before, in practice, you would probably only use scale $(a b)$ when applying the scaling rules from a previous analysis. Allowing fp to scale does have the advantage of not altering the original variable, weight.

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
```

. fp <weight>, fp(-.5) scale(0 1000) : regress mpg <weight> foreign
-> regress mpg weight_1 foreign

| Source | SS | df | MS | Number of obs | = | 74 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathrm{F}(2,71)$ | = | 79.51 |
| Model | 1689.20861 | 2 | 844.604307 | Prob > F | = | 0.0000 |
| Residual | 754.250846 | 71 | 10.6232514 | R -squared | = | 0.6913 |
|  |  |  |  | Adj R-squared | = | 0.6826 |
| Total | 2443.45946 | 73 | 33.4720474 | Root MSE | = | 3.2593 |

| mpg | Coefficient | Std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | $[95 \%$ conf. interval] |  |
| ---: | ---: | :--- | :---: | :---: | ---: | ---: |
| weight_1 | 66.89665 | 6.021749 | 11.11 | 0.000 | 54.88963 | 78.90368 |
| foreign | -2.095622 | 1.043513 | -2.01 | 0.048 | -4.176329 | -.0149159 |
| _cons | -17.58651 | 3.397992 | -5.18 | 0.000 | -24.36192 | -10.81111 |

The scaling is clearly indicated in the variable notes for the generated variable weight_1.

```
. notes weight_1
weight_1:
    1. fp term 1 of }\mp@subsup{x}{}{\wedge}(-.5), where x is weight scaled.
    2. Scaling was user specified: x = (weight+a)/b where a=0 and b=1000
    3. Fractional polynomial variables created by fp <weight>, fp(-.5)
        scale(0 1000): regress mpg <weight> foreign
    4. To re-create the fractional polynomial variables, for instance, in
        another dataset, type fp gen double weight`(-.5), scale(0 1000)
```

## Centering

The fractional polynomial of term, centered on $c$ is

$$
\left(\operatorname{term}^{\left(p_{1}, \ldots, p_{m}\right)}-c^{\left(p_{1}, \ldots, p_{m}\right)}\right)^{\prime} \boldsymbol{\beta}
$$

The intercept of a centered fractional polynomial can be interpreted as the effect at zero for all the covariates. When we center the fractional polynomial terms using $c$, the intercept is now interpreted as the effect at term $=c$ and zero values for the other covariates.

Suppose we wanted to center the fractional polynomial of $x$ with powers $(0,0,2)$ at $x=c$.

$$
\begin{aligned}
& \left(x^{(0,0,2)}-c^{(0,0,2)}\right)^{\prime} \boldsymbol{\beta} \\
& =\beta_{0}+\beta_{1}\left(x^{(0)}-c^{(0)}\right)+\beta_{2}\left\{x^{(0)} \ln (x)-c^{(0)} \ln (c)\right\}+\beta_{3}\left(x^{(2)}-c^{(2)}\right) \\
& =\beta_{0}+\beta_{1}\{\ln (x)-\ln (c)\}+\beta_{2}\left[\{\ln (x)\}^{2}-\{\ln (c)\}^{2}\right]+\beta_{3}\left(x^{2}-c^{2}\right)
\end{aligned}
$$

When center is specified, fp centers based on the sample mean of (scaled) term. A previously chosen value for centering, $c$, may also be specified in center ( $c$ ). This would be done when applying the results of a previous model fitting to a new dataset.

The center and center (c) options may be used in fp or fp generate.
Returning to the model of mileage per gallon based on automobile weight and foreign origin, we refit the model with the fractional polynomial of weight centered at its scaled mean.

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. fp <weight>, fp(-.5) scale(0 1000) center: regress mpg <weight> foreign
-> regress mpg weight_1 foreign
```

| Source | SS | df | MS | Number of obs | = | 74 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathrm{F}(2,71)$ | = | 79.51 |
| Model | 1689.20861 | 2 | 844.604307 | Prob > F | = | 0.0000 |
| Residual | 754.250846 | 71 | 10.6232514 | R-squared | = | 0.6913 |
|  |  |  |  | Adj R-squared | = | 0.6826 |
| Total | 2443.45946 | 73 | 33.4720474 | Root MSE | = | 3.2593 |

| mpg | Coefficient | Std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | $[95 \%$ conf. interval] |  |
| ---: | ---: | :--- | :---: | :---: | ---: | ---: |
| weight_1 | 66.89665 | 6.021749 | 11.11 | 0.000 | 54.88963 | 78.90368 |
| foreign | -2.095622 | 1.043513 | -2.01 | 0.048 | -4.176329 | -.0149159 |
| _cons | 20.91163 | .4624143 | 45.22 | 0.000 | 19.9896 | 21.83366 |

Note that the coefficients for weight_1 and foreign do not change. Only the intercept _cons changes. It can be interpreted as the estimated average miles per gallon of an American-made car of average weight.

## Examples

> Example 1: Linear regression
Consider the serum immunoglobulin G (IgG) dataset from Isaacs et al. (1983), which consists of 298 independent observations in young children. The dependent variable sqrtigg is the square root of the IgG concentration, and the independent variable age is the age of each child. (Preliminary Box-Cox analysis shows that a square root transformation removes the skewness in IgG.)

The aim is to find a model that accurately predicts the mean of sqrtigg given age. We use $f p$ to find the best FP2 model (the default option). We specify center for automatic centering. The age of each child is small in magnitude and positive, so we do not use the scaling options of $f p$ or scale ourselves.

```
. use https://www.stata-press.com/data/r18/igg, clear
(Immunoglobulin in children)

The new variables created by fp contain the best-fitting fractional polynomial powers of age, as centered by $f p$. For example, age_1 is centered by subtracting the mean of age raised to the power -2 .

The variables created by $f p$ and $f p$ generate are centered or scaled as specified by the user, which is reflected in the estimated regression coefficients and intercept. Centering does have its advantages (see Centering earlier in this entry). By default, $f p$ will not perform scaling or centering. For a more detailed discussion, see Royston and Sauerbrei (2008, sec. 4.11).

The fitted curve has an asymmetric $S$ shape. The best model has powers $(-2,2)$ and deviance 319.448. We reject lesser degree models: the null, linear, and natural $\log$ power models at the 0.05 level. As many as 44 models have been fit in the search for the best powers. Now let's look at
models of degree $\leq 4$. The highest allowed degree is specified in dimension(). We overwrite the previously generated fractional polynomial power variables by including replace.

```

It appears that the FP4 model is not significantly different from the other fractional polynomial models (at the 0.05 level).

Let's compare the curve shape from the $m=2$ model with that from a conventional quartic polynomial whose fit turns out to be significantly better than a cubic (not shown). We use the ability of $f p$ both to generate the required powers of age, namely, $(1,2,3,4)$ for the quartic and $(-2,2)$ for the second-degree fractional polynomial, and to fit the model. The fp() option is used to specify the powers. We use predict to obtain the fitted values of each regression. We fit both models with fp and graph the resulting curves with twoway scatter.

```

> lpattern(. __.) ytitle("Square root of IgG") xtitle("Age (years)")

The quartic curve has an unsatisfactory wavy appearance that is implausible for the known behavior of IgG, the serum level of which increases throughout early life. The fractional polynomial curve (FP2) increases monotonically and is therefore biologically the more plausible curve. The two models have approximately the same deviance.

## > Example 2: Cox regression

Data from Smith et al. (1992) contain times to complete healing of leg ulcers in a randomized, controlled clinical trial of two treatments in 192 elderly patients. Several covariates were available, of which an important one is mthson, the number of months since the recorded onset of the ulcer. This time is recorded in whole months, not fractions of a month; therefore, some zero values are recorded.

Because the response variable is time to an event of interest and some (in fact, about one-half) of the times are censored, using Cox regression to analyze the data is appropriate. We consider fractional polynomials in mthson, adjusting for four other covariates: age; ulcarea, the area of tissue initially affected by the ulcer; deepppg, a binary variable indicating the presence or absence of deep vein involvement; and treat, a binary variable indicating treatment type.

We fit fractional polynomials of degrees 1 and 2 with fp . We specify scale to perform automatic scaling on mthson. This makes it positive and ensures that its magnitude is not too large. (See Scaling for more details.) The display option nohr is specified before the colon so that the coefficients and not the hazard ratios are displayed.

The center option is specified to obtain automatic centering. age and ulcarea are also demeaned by using summarize and then subtracting the returned result $r$ (mean).

In Cox regression, there is no constant term, so we cannot see the effects of centering in the table of regression estimates. The effects would be present if we were to graph the baseline hazard or survival function because these functions are defined with all predictors set equal to 0 .

In these graphs, we will see the estimated baseline hazard or survival function under no deep vein involvement or treatment and under mean age, ulcer area, and number of months since the recorded onset of the ulcer.

Fractional polynomial comparisons:

The best-fitting fractional polynomial of degree 2 has powers $(0.5,0.5)$ and deviance 736.709 . However, this model does not fit significantly better than the fractional polynomial of degree 1 (at the 0.05 level), which has power -0.5 and deviance 738.969. We prefer the model with $m=1$.

The hazard for healing is much higher for patients whose ulcer is of recent onset than for those who have had an ulcer for many months.

A more appropriate analysis of this dataset, if one wanted to model all the predictors, possibly with fractional polynomial functions, would be to use $m f p$; see $[R] \mathbf{m f p}$.

## > Example 3: Logistic regression

The zero option permits fitting a fractional polynomial model to the positive values of a covariate, taking nonpositive values as zero. An application is the assessment of the effect of cigarette smoking as a risk factor. Whitehall 1 is an epidemiological study, which was examined in Royston and Sauerbrei (2008), of 18,403 male British Civil Servants employed in London. We examine the data collected in Whitehall 1 and use logistic regression to model the odds of death based on a fractional polynomial in the number of cigarettes smoked.

Nonsmokers may be qualitatively different from smokers, so the effect of smoking (regarded as a continuous variable) may not be continuous between zero cigarettes and one cigarette. To allow for this possibility, we model the risk as a constant for the nonsmokers and as a fractional polynomial function of the number of cigarettes for the smokers, adjusted for age.

The dependent variable all 10 is an indicator of whether the individual passed away in the 10 years under study. cigs is the number of cigarettes consumed per day. After loading the data, we demean age and create a dummy variable, nonsmoker. We then use $f p$ to fit the model.

```
. use https://www.stata-press.com/data/r18/smoking, clear
(Smoking and mortality data)
. quietly sum age
. replace age = age - r(mean)
variable age was byte now float
(17,260 real changes made)
. generate byte nonsmoker = cond(cigs==0, 1, 0) if cigs < .
. fp <cigs>, zero: logit all10 <cigs> nonsmoker age
(fitting 44 models)
( . . . 10% . . . 20% . . . . 30% . . . 40% . . . 50% . . . . 60% . . . . 70% . . . . 80% . . . . 90% . . . . 100%%)
```

Fractional polynomial comparisons:

| cigs | Test <br> df | Deviance | Deviance <br> diff. | P | Powers |

| age | .1194541 | .0045818 | 26.07 | 0.000 | .1104739 | .1284343 |
| _cons | -1.591489 | .1052078 | -15.13 | 0.000 | -1.797693 | -1.385286 |

Omission of the zero option would cause $f p$ to halt with an error message because nonpositive covariate values (for example, values of cigs) are invalid unless the scale option is specified.

A closely related approach involves the catzero option. Here we no longer need to have nonsmoker in the model, because $f p$ creates its own dummy variable cigs_0 to indicate whether the individual does not smoke on that day.

```
. fp <cigs>, catzero replace: logit all10 <cigs> age
(fitting 44 models)
( . . . 10% . . . 20% . . . . 30% . . . 40% . . . 50% . . . . 60% . . . . 70% . . . . 80% . . . 90% . . . 100%)
```

Fractional polynomial comparisons:

| cigs | Test <br> df | Deviance | Deviance <br> diff. | P | Powers |

| omitted | 5 | 10175.75 | 231.047 | 0.000 |  |
| linear | 3 | 9958.80 | 14.093 | 0.003 | 1 |
| m $=1$ | 2 | 9946.60 | 1.895 | 0.388 | 0 |
| $\mathrm{~m}=2$ | 0 | 9944.71 | 0.000 | -- | $-1-1$ |

Note: Test df is degrees of freedom, and $\mathbf{P}=\mathrm{P}>$ chi2 is sig. level
for tests comparing models vs. model with $m=2$ based on deviance difference, chi2.
Logistic regression $\quad$ Number of obs $=17,260$
LR chi2(4) $=1029.03$
Prob > chi2 $=0.0000$
Pseudo R2 $=0.0938$

| all10 | Coefficient | Std. err. | $z$ | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| cigs_0 | -1.223749 | .1119583 | -10.93 | 0.000 | -1.443183 | -1.004315 |
| cigs_1 | -1.285867 | .3358483 | -3.83 | 0.000 | -1.944117 | -.6276162 |
| cigs_2 | -1.982424 | .572109 | -3.47 | 0.001 | -3.103736 | -.8611106 |
| age | .1194541 | .0045818 | 26.07 | 0.000 | .1104739 | .1284343 |
| _cons | -1.591489 | .1052078 | -15.13 | 0.000 | -1.797693 | -1.385286 |

Under both approaches, the comparison table suggests that we can accept the FP1 model instead of the FP2 model. We estimate the parameters of the accepted model-that is, the one that uses the natural logarithm of cigs-with fp.

| . fp <cigs>, catzero replace fp(0): logit all10 <cigs> age |  |
| :--- | :--- |
| -> logit allio cigs_0 cigs_1 age |  |
| Logistic regression | Number of obs $=17,260$ |
|  | LR chi2 (3) $=1027.13$ |
|  | Prob $>$ chi2 $=0.0000$ |
| Log likelihood $=-4973.3016$ | Pseudo R2 $=0.0936$ |

| all10 | Coefficient | Std. err. | $z$ | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| cigs_0 | .1883732 | .1553093 | 1.21 | 0.225 | -.1160274 | .4927738 |
| cigs_1 | .3469842 | .0543552 | 6.38 | 0.000 | .2404499 | .4535185 |
| age | .1194976 | .0045818 | 26.08 | 0.000 | .1105174 | .1284778 |
| _cons | -3.003767 | .1514909 | -19.83 | 0.000 | -3.300683 | -2.70685 |

The high $p$-value for cigs_0 in the output indicates that we cannot reject that there is no extra effect at zero for nonsmokers.

## Stored results

## Methods and formulas

The general definition of a fractional polynomial, accommodating possible repeated powers, may be written for functions $H_{1}(x), \ldots, H_{m}(x)$ of $x>0$ as

$$
\beta_{0}+\sum_{j=1}^{m} \beta_{j} H_{j}(x)
$$

where $H_{1}(x)=x^{\left(p_{1}\right)}$ and for $j=2, \ldots, m$,

$$
H_{j}(x)= \begin{cases}x^{\left(p_{j}\right)} & \text { if } p_{j} \neq p_{j-1} \\ H_{j-1}(x) \ln (x) & \text { if } p_{j}=p_{j-1}\end{cases}
$$

For example, a fractional polynomial of degree 3 with powers $(1,3,3)$ has $H_{1}(x)=x, H_{2}(x)=x^{3}$, and $H_{3}(x)=x^{3} \ln (x)$ and equals $\beta_{0}+\beta_{1} x+\beta_{2} x^{3}+\beta_{3} x^{3} \ln (x)$.

We can express a fractional polynomial in vector notation by using $\mathbf{H}(x)=\left[H_{1}(x), \ldots, H_{d}(x)\right]^{\prime}$. We define $x^{\left(p_{1}, p_{2}, \ldots, p_{m}\right)}=\left[\mathbf{H}(x)^{\prime}, 1\right]^{\prime}$. Under this notation, we can write

$$
x^{(1,3,3) \prime} \boldsymbol{\beta}=\beta_{0}+\beta_{1} x+\beta_{2} x^{3}+\beta_{3} x^{3} \ln (x)
$$

The fractional polynomial may be centered so that the intercept can be more easily interpreted. When centering the fractional polynomial of $x$ at $c$, we subtract $c^{\left(p_{1}, p_{2}, \ldots, p_{m}\right)}$ from $x^{\left(p_{1}, p_{2}, \ldots, p_{m}\right)}$, where $c^{\left(p_{1}, p_{2}, \ldots, p_{d}\right)}=\left[\mathbf{H}(x)^{\prime}, 0\right]^{\prime}$. The centered fractional polynomial is

$$
\left(x^{\left(p_{1}, \ldots, p_{d}\right)}-c^{\left(p_{1}, \ldots, p_{d}\right)}\right)^{\prime} \boldsymbol{\beta}
$$

The definition may be extended to allow $x \leq 0$ values. For these values, the fractional polynomial is equal to the intercept $\beta_{0}$ or equal to a zero-offset term $\alpha_{0}$ plus the intercept $\beta_{0}$.

The deviance $D$ of a model is defined as -2 times its maximized log likelihood. For normal error models, we use the formula

$$
D=n\left(1-\bar{l}+\ln \frac{2 \pi \mathrm{RSS}}{n}\right)
$$

where $n$ is the sample size, $\bar{l}$ is the mean of the lognormalized weights ( $\bar{l}=0$ if the weights are all equal), and RSS is the residual sum of squares as fit by regress.

When fp is used to search for the best combination of powers, it reports a table comparing fractional polynomial models of degree $k<m$ with the degree $m$ fractional polynomial model, which will have the lowest deviance. The comparison table also includes the linear model, in which <term> is not raised to a power, and the null model, in which <term> is omitted.

The Test df column of the model comparison table does not correspond to the model degrees of freedom for the individual models but rather to the degrees of freedom of a test comparing that model with the model with the lowest deviance. For normal error models, this is the numerator degrees of freedom of a partial $F$ test; for other models, it is the degrees of freedom of the likelihood-ratio $\chi^{2}$ test. When calculating the test degrees of freedom, the command accounts for the two types of parameters that are being estimated by fp : coefficients $\left(\beta_{j}\right)$ and powers. Because the powers in a fractional polynomial are chosen from a finite set rather than from the entire real line, the degrees of freedom defined in this way are approximate and generally yield somewhat conservative tests (Royston and Altman 1994).

The $p$-values reported by fp are calculated differently for normal error models than for other models. Let $D_{k}$ and $D_{m}$ be the deviances of the models with degrees $k$ and $m$, respectively. For normal error models, a variance ratio $F$ is calculated as

$$
F=\frac{d_{2}}{d_{1}}\left\{\exp \left(\frac{D_{k}-D_{m}}{n}\right)-1\right\}
$$

where $d_{1}$ is the numerator df , the number of additional parameters estimated by the degree $m$ model over the degree $k$ model. $d_{2}$ is the denominator degrees of freedom and equals the residual degrees of freedom of the degree $m$ model minus the number of powers estimated, $m$. The $p$-value is obtained by referring $F$ to an $F$ distribution on $\left(d_{1}, d_{2}\right) \mathrm{df}$.

For nonnormal models, the $p$-value is obtained by referring $D_{k}-D_{m}$ to a $\chi^{2}$ distribution on $d_{1}$ degrees of freedom, with $d_{1}$ defined as above.

## Acknowledgment

We thank Patrick Royston of the MrC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model for writing fracpoly and fracgen, the commands on which $f p$ and $f p$ generate are based. We also thank Professor Royston for his advice on and review of the new $f p$ commands.

## Postestimation commands

The following postestimation commands are of special interest after $f p$ :
Command Description
fp plot component-plus-residual plot from most recently fit fractional polynomial model
fp predict create variable containing prediction or SEs of fractional polynomials

The following standard postestimation commands are also available if available after est_cmd:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| forecast | dynamic forecasts and simulations |
| hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| linktest | link test for model specification |
| lrtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | predictions, residuals, influence statistics, and other diagnostic measures |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| suest | seemingly unrelated estimation |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

## predict

The behavior of predict following fp is determined by est_cmd. See the corresponding est_cmd postestimation entry for available predict options.

Also see information on fp predict below.

## margins

The behavior of margins following fp is determined by est_cmd. See the corresponding est_cmd postestimation entry for available margins options.

## fp plot and fp predict

## Description for fp plot and fp predict

fp plot produces a component-plus-residual plot. The fractional polynomial comprises the component, and the residual is specified by the user in residuals (). The component-plus-residuals are plotted against the fractional polynomial variable. If you only want to plot the component fit, without residuals, you would specify residuals(none).
fp predict generates the fractional polynomial or the standard error of the fractional polynomial. The fractional polynomial prediction is equivalent to the fitted values prediction given by predict, xb , with the covariates other than the fractional polynomial variable set to zero. The standard error may be quite large if the range of the other covariates is far from zero. In this situation, the covariates would be centered and their range would include, or come close to including, zero.

These postestimation commands can be used only when the fractional polynomial variables do not interact with other variables in the specification of est_cmd. See [U] 11.4.3 Factor variables for more information about interactions.

## Menu for fp plot and fp predict

## fp plot

Statistics $>$ Linear models and related $>$ Fractional polynomials $>$ Component-plus-residual plot

## fp predict

Statistics $>$ Linear models and related $>$ Fractional polynomials $>$ Fractional polynomial prediction

## Syntax for fp plot and fp predict

Component-plus-residual plot for most recently fit fractional polynomial model
fp plot [if] [in], residuals(res_option) [graph_options]

Create variable containing the prediction or SEs of fractional polynomials
fp predict [type] newvar [if] [in] [, predict_options]

## graph_options

Description

## Main

*residuals(res_option)
residual option name to use in predict after est_cmd, or residuals (none) if residuals are not to be graphed
equation (eqno)
specify equation
level(\#)
set confidence level; default is level (95)
Plot
plotopts(scatter_options) affect rendition of the component-plus-residual scatter points
Fitted line
lineopts (cline_options) affect rendition of the fitted line
Cl plot
ciopts (area_options) affect rendition of the confidence bands
Add plots
addplot (plot) add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall
twoway_options
any options other than by () documented in [G-3] twoway_options
${ }^{*}$ residuals(res_option) is required.
predict_options
Description
Main
fp calculate the fractional polynomial; the default
stdp
equation(eqno)
calculate the standard error of the fractional polynomial specify equation

## Options for fp plot

Main
residuals (res_option) specifies what type of residuals to plot in the component-plus-residual plot. res_option is the same option that would be specified to predict after est_cmd. Residuals can be omitted from the plot by specifying residuals (none). residuals () is required.
equation (eqno) is relevant only when you have previously fit a multiple-equation model in est_cmd. It specifies the equation to which you are referring.
equation(\#1) would mean that the calculation is to be made for the first equation, equation(\#2) would mean the second, and so on. You could also refer to the equations by their names: equation(income) would refer to the equation named income, and equation(hours) would refer to the equation named hours.

## Options for fp predict

$\qquad$ Main
fp calculates the fractional polynomial, the linear prediction with other variables set to zero. This is the default.
stdp calculates the standard error of the fractional polynomial.
equation (eqno) is relevant only when you have previously fit a multiple-equation model in est_cmd. It specifies the equation to which you are referring.
equation(\#1) would mean that the calculation is to be made for the first equation, equation(\#2) would mean the second, and so on. You could also refer to the equations by their names: equation(income) would refer to the equation named income, and equation(hours) would refer to the equation named hours.
If you do not specify equation(), the results are the same as if you specified equation(\#1).

## Remarks and examples

After a model is fit using $f p$, the estimated fractional polynomial may be of interest. This is the linear combination of the fractional polynomial terms and the constant intercept using the model coefficients estimated by fp . It is equivalent to the fitted values prediction given by predict, xb , with the covariates and the fractional polynomial variable set to zero. When these other covariates have been centered, the prediction is made at the centering values of the covariates.

A component-plus-residual plot is generated by fp plot. The fractional polynomial comprises the component, and the residual is specified by the user in residuals(). The residuals() option takes the same argument that would be supplied to predict after est_cmd to obtain the desired type of residuals. If you only want to plot the component fit, without residuals, you would specify residuals(none).
fp predict generates the fractional polynomial. If the stdp option is specified, the standard error of the fractional polynomial is generated instead. This standard error may be quite large if the range of the other covariates is far from zero. In this situation, the covariates would be centered and their range would include, or come close to including, zero.

These postestimation commands can be used only when the fractional polynomial terms do not interact with other variables in the specification of est_cmd. See [U] 11.4.3 Factor variables for more information about interactions.

## Examples

$>$ Example 1: fp plot after linear regression
In example 1 of [R] fp, we modeled the mean of the square root of a child's serum immunoglobulin $\mathrm{G}(\mathrm{IgG})$ level as a fractional polynomial function of the child's age. An FP2 model with powers $(-2,2)$ is chosen.

We load the data and then fit the model with $f p$. Then, we use $f p$ plot to draw the component-plus-residual plot. A $95 \%$ confidence interval is produced for the fractional polynomial in age (the component). The residuals prediction option for regress is specified in the residuals() option in $f p$ plot so that the residuals are rendered.

```
. use https://www.stata-press.com/data/r18/igg
(Immunoglobulin in children)
. fp <age>, scale center: regress sqrtigg <age>
    (output omitted)
. fp plot, residuals(residuals)
```

## > Example 2: fp plot after Cox regression

In example 2 of $[\mathrm{R}] \mathbf{f p}$, we modeled the time to complete healing of leg ulcers for 192 elderly patients using a Cox regression. A one-degree fractional polynomial in mthson, the number of months since the onset of the ulcer, is used as a predictor in the regression. The power -0.5 is used for mthson. Other covariates are age (age), ulcer area (ulcarea), treatment type, and a binary indicator of deep vein involvement (deepppg).

We load the data and then demean ulcer area and age. Then, we fit the model with $f p$ and draw the component-plus-residual plot with fp plot. mgale is specified in the residuals() option to obtain martingale residuals. See [ST] stcox postestimation for more details.

```
. use https://www.stata-press.com/data/r18/legulcer2, clear
(Leg ulcer clinical trial)
. quietly stset ttevent, failure(healed)
. quietly summarize age
. replace age = age - r(mean)
variable age was byte now float
(192 real changes made)
. quietly summarize ulcarea
. replace ulcarea = ulcarea - r(mean)
variable ulcarea was int now float
(192 real changes made)
. fp <mthson>, replace center scale nohr fp(-.5): stcox <mthson> age ulcarea
> deepppg treat
    (output omitted)
fp plot, residuals(mgale)
```

## Example 3: fp plot and fp predict after logistic regression

In example 3 of [R] fp, we used logistic regression to model the odds of death for male civil servants in Britain conditional on cigarette consumption. The dependent variable all10 is an indicator of whether the individual passed away in the 10 years under study.

Nonsmokers may be qualitatively different from smokers, so the effect of smoking (regarded as a continuous variable) may not be continuous between zero cigarettes and one cigarette. To allow for this possibility, we model the risk as constant intercept for the nonsmokers and as a fractional polynomial function of the number of cigarettes for the smokers, cigs, adjusted for age. An FP1 model with power 0 is chosen.

We load the data and demean age. Then, we fit the model using $f p$ and graph the fit of the model and $95 \%$ confidence interval using fp plot. Only the component fit is graphed by specifying residuals(none).

```
. use https://www.stata-press.com/data/r18/smoking, clear
(Smoking and mortality data)
. quietly summarize age
. replace age = age - r(mean)
variable age was byte now float
(17,260 real changes made)
. fp <cigs>, catzero replace fp(0): logit all10 <cigs> age
-> logit all10 cigs_0 cigs_1 age
Logistic regression Number of obs = 17,260
                                    LR chi2(3) = 1027.13
                                    Prob > chi2 = 0.0000
                                    Pseudo R2 = 0.0936
```

| all10 | Coefficient | Std. err. | $z$ | P>\|z| | [95\% conf. interval] |  |

[^27]

We see a small spike at zero for cigs because of the effect of cigs_0 on the fractional polynomial; however, the high $p$-value for cigs_0 in the model output indicates that we cannot reject that there is no extra effect at zero for nonsmokers.

We can also use fp predict to predict the fractional polynomial for nonsmokers and the mean of age. This is the value at the spike. We store the result in fpO . We see it is equivalent to the sum of the constant intercept estimate and the estimate of the cigs_0 coefficient.

```
. fp predict fpO if cigs == 0
(7,157 missing values generated)
. summarize fp0
\begin{tabular}{r|rrrrr} 
Variable & Obs & Mean & Std. dev. & Min & Max \\
\hline fp0 & 10,103 & -2.815393 & & 0 & -2.815393
\end{tabular}
. display _b[cigs_0]+_b[_cons]
-2.8153935
```

## Methods and formulas

Let the data consist of triplets $\left(y_{i}, x_{i}, \mathbf{z}_{i}\right), i=1, \ldots, n$, where $\mathbf{z}_{i}$ is the vector of covariates for the $i$ th observation and $x_{i}$ is the fractional polynomial variable.
fp predict calculates the fractional polynomial at the centering value $x_{0}, \widehat{\eta}_{i}=\left(x_{i}{ }^{\left(p_{1}, \ldots, p_{d}\right)}-\right.$ $\left.x_{0}{ }^{\left(p_{1}, \ldots, p_{m}\right)}\right)^{\prime} \widehat{\boldsymbol{\beta}}$. This is equivalent to the linear predictor of the model at $\mathbf{z}_{i}=\mathbf{0}$. The standard error is calculated from the variance-covariance matrix of $\widehat{\boldsymbol{\beta}}$, ignoring estimation of the powers. When $x_{i} \leq 0, \mathbf{H}\left(x_{i}\right)$, and thus $x_{i}{ }^{\left(p_{1}, \ldots, p_{m}\right)}$, is either undefined or zero. A zero offset term, $\alpha_{0}$, may be added to $\widehat{\eta}_{i}$ for these nonpositive $x_{i}$ values.

The values $\widehat{\eta}_{i}$ represent the behavior of the fractional polynomial model for $x$ at fixed values $\mathbf{z}=\mathbf{0}$ of the (centered) covariates. The $i$ th component-plus-residual is defined as $\widehat{\eta}_{i}+d_{i}$, where $d_{i}$ is the residual for the $i$ th observation. The definition of $d_{i}$ will change according to the type of model used and the preference of the user. fp plot plots $\widehat{\eta}_{i}+d_{i}$ versus $x_{i}$, overlaying $\widehat{\eta}_{i}$ and its confidence interval.

## Acknowledgment

We thank Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model for writing fracplot and fracpred, the commands on which fp plot and fp predict are based. We also thank Professor Royston for his advice on and review of $f p$ plot and fp predict.

## Description

fracreg fits a fractional response model for a dependent variable that is greater than or equal to 0 and less than or equal to 1 . It uses a probit, logit, or heteroskedastic probit model for the conditional mean. These models are often used for outcomes such as rates, proportions, and fractional data.

## Quick start

Fractional probit model for y with values between 0 and 1 on continuous variable x 1
fracreg probit y x1
Same as above, but use logit distribution
fracreg logit y x1
Fractional probit model for y on x 1 and use x 2 to model the variance of y
fracreg probit $y$ x1, het(x2)

do not display the coefficient table; seldom used
keep collinear variables
display legend instead of statistics
*het () may be used only with fracreg probit to compute fractional heteroskedastic probit regression. indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bayes, bootstrap, by, collect, fp, jackknife, mi estimate, rolling, statsby, and svy are allowed; see
[U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: fracreg.
vce (bootstrap) and vce (jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
vce(), nocoef, and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
nocoef, collinear, and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

$\qquad$ Model
noconstant, offset (varname), constraints (constraints); see [R] Estimation options. het (varlist $\left[\right.$, offset $\left(\right.$ varname $\left.\left._{o}\right)\right]$ ) specifies the independent variables and, optionally, the offset variable in the variance function. het() may only be used with fracreg probit to compute fractional heteroskedastic probit regression.
offset ( varname $_{o}$ ) specifies that selection offset varname ${ }_{o}$ be included in the model with the coefficient constrained to be 1 .

## SE/Robust

vce (vcetype) specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
level(\#); see [R] Estimation options.
or reports the estimated coefficients transformed to odds ratios, that is, $e^{b}$ rather than $b$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or may be specified at estimation or when replaying previously estimated results. This option may only be used with fracreg logit.
nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% fint), and nolstretch; see [R] Estimation options.

Maximization
maximize_options: difficult, technique (algorithm_spec), iterate(\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance(\#), nonrtolerance, and from (init_specs); see [R] Maximize. These options are seldom used.

The following options are available with fracreg but are not shown in the dialog box:
nocoef specifies that the coefficient table not be displayed. This option is sometimes used by programmers but is of no use interactively.
collinear, coeflegend; see [R] Estimation options.

## Remarks and examples

Fractional response data may occur when the outcome of interest is measured as a fraction, for example, a patient's oxygen saturation or Gini coefficient values. These data are also often observed when proportions are generated from aggregated binary outcomes. For example, rather than having data on whether individual students passed an exam, we might simply have data on the proportion of students in each school that passed.

These models are appropriate when you have a dependent variable that takes values between 0 and 1 and may also be equal to 0 or 1 , denoted for conciseness with the notation $[0,1]$. If the dependent variable takes only values between 0 and 1, betareg might be a valid alternative. betareg provides more flexibility in the distribution of the mean of the dependent variable but is misspecified if the dependent variable is equal to 0 or 1 . See $[R]$ betareg for more information.

These models have been applied to various topics. For example, Papke and Wooldridge (1996) studied the participation rates of employees in firms' 401(k) retirement plans. Papke and Wooldridge (2008) also evaluated an education policy by studying the pass rates for an exam administered to fourth grade Michigan students over time.

The models fit by fracreg are quasilikelihood estimators like the generalized linear models described in $[R]$ glm. Fractional regression is a model of the mean of the dependent variable $y$ conditional on covariates $\mathbf{x}$, which we denote by $\mu_{\mathbf{x}}$. Because $y$ is in $[0,1]$, we must ensure that $\mu_{\mathbf{x}}$ is also in $[0,1]$. We do this by using a probit, logit, or heteroskedastic probit model for $\mu_{\mathbf{x}}$.

The key insight from quasilikelihood estimation is that you do not need to know the true distribution of the entire model to obtain consistent parameter estimates. In fact, the only information that you need is the correct specification of the conditional mean.

This means that the true model does not need to be, for example, a probit. If the true model is a probit, then fitting a probit regression via maximum likelihood gives you consistent parameter estimates and asymptotically efficient standard errors.

By contrast, if the conditional mean of the model is the same as the conditional mean of a probit but the model is not a probit, the point estimates are consistent, but the standard errors are not asymptotically efficient. The standard errors are not efficient, because no assumptions about the distribution of the unobserved components in the model are made. Thus fracreg uses robust standard errors by default.

For further discussion on quasilikelihood estimation in the context of fractional regression, please see Papke and Wooldridge (1996) and Wooldridge (2010).

## > Example 1: Fractional probit model of rates

In this example, we look at the expected participation rate in $401(\mathrm{k})$ plans for a cross-section of firms. Participation rate (prate) is defined as the fraction of eligible employees in a firm that participate in a $401(\mathrm{k})$ plan. We use summarize to see the range of the participation rate.

```
. use https://www.stata-press.com/data/r18/401k
(Firm-level data on 401k participation)
```

- summarize prate

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| prate | 4,075 | .840607 | .1874841 | .0036364 | 1 |

The variable has values between 0 and 1 but also has at least 1 firm for which the participation rate is exactly 1 .

As in Papke and Wooldridge (1996), we surmise that the expected participation rate depends on the matching rate of employee $401(\mathrm{k})$ contributions (mrate), the natural $\log$ of the total number of employees (ltotemp), the age of the plan (age), and whether the $401(\mathrm{k})$ plan is the only retirement plan offered by the employer (sole). We include ltotemp and age, along with their squares, using factor-variable notation; see [U] 11.4.3 Factor variables.

If we believe that the functional form of the expected participation rate is a cumulative normal density, we may use fracreg probit.

Like those obtained from probit, the parameters provide the sign of the marginal effect of the covariates on the outcome, but the magnitude is difficult to interpret. We can use margins to estimate conditional or population-averaged effects; see example 2. The standard errors are robust by default because the true data-generating process need not be a probit, even though we use the probit likelihood to obtain our parameter estimates.

## > Example 2: Changing the distribution of the conditional mean

Continuing with example 1, we may instead believe that the expected participation rate follows a fractional logistic response. In this case, we should use fractional logistic regression instead of fractional probit regression to obtain consistent estimates of the parameters of the conditional mean.

Like those obtained from logit, the parameters provide the sign of the marginal effect of the covariates on the outcome, but the magnitude is again difficult to interpret. As with fracreg probit in example 1, we would use margins to obtain the marginal effects or other predictions of interest.
> Example 3: Odds ratios from a fractional logit model
When the conditional mean of our outcome is interpretable as a probability, it is possible to adopt an odds-ratio interpretation of the results of a fractional logit model. In example 2, this is plausible because expected participation rates can be viewed as estimates of the probability of participation. We obtain the odds ratios by specifying the option or.

```
Note: _cons estimates baseline odds.
```

Among other things, we see that if the $401(\mathrm{k})$ is the only plan offered by the employer, then the odds of an employee participating increase by a factor of 1.12 . We can also see that if the matching rate goes from 0 to $1: 1$ (exactly matching employee contributions) or from $1: 1$ to $2: 1$ (doubling employee contributions), then the odds of participating increase by 3.1.

The use of an odds-ratio interpretation is not appropriate if the conditional mean cannot be viewed as a probability. For example, if the fractional outcome were a Gini coefficient, we could not interpret the expected values of our outcomes as probabilities. The Gini coefficient is a measure of inequality between zero and one and cannot be interpreted as a probability. In this case, using the odds-ratio option would not be sensible.

## fracreg

command as typed
model for conditional mean; logit, probit, or hetprobit
name of dependent variable
weight type
weight expression
title in estimation output
name of cluster variable
offset
Wald; type of model $\chi^{2}$ test
vcetype specified in vce()
title used to label Std. err.
type of optimization
max or min; whether optimizer is to perform maximization or minimization
type of ml method
name of likelihood-evaluator program
maximization technique
b V
program used to implement estat
program used to implement predict
predictions disallowed by margins
factor variables fvset as asbalanced
factor variables fvset as asobserved
coefficient vector
vector of means of the independent variables
constraints matrix
iteration $\log$ (up to 20 iterations)
gradient vector
variance-covariance matrix of the estimators
model-based variance
marks estimation sample

In addition to the above, the following is stored in r() :
Matrices
$r$ (table)
matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

The log-likelihood function for fractional models is of the form

$$
\ln L=\sum_{j=1}^{N} w_{j} y_{j} \ln \left\{G\left(\mathbf{x}_{j}^{\prime} \boldsymbol{\beta}\right)\right\}+w_{j}\left(1-y_{j}\right) \ln \left\{1-G\left(\mathbf{x}_{j}^{\prime} \boldsymbol{\beta}\right)\right\}
$$

where $N$ is the sample size, $y_{j}$ is the dependent variable, $w_{j}$ denotes the optional weights, $\ln L$ is maximized, as described in [R] Maximize, and $G(\cdot)$ can be

| Model | Functional form for $G\left(\mathbf{x}_{j}^{\prime} \boldsymbol{\beta}\right)$ |
| :---: | :---: |
| probit | $\Phi\left(\mathbf{x}_{j}^{\prime} \boldsymbol{\beta}\right)$ |
| logit | $\exp \left(\mathbf{x}_{j}^{\prime} \boldsymbol{\beta}\right) /\left\{1+\exp \left(\mathbf{x}_{j}^{\prime} \boldsymbol{\beta}\right)\right\}$ |
| hetprobit | $\Phi\left\{\mathbf{x}_{j}^{\prime} \boldsymbol{\beta} / \exp \left(\mathbf{z}_{j}^{\prime} \boldsymbol{\gamma}\right)\right\}$ |

where $\mathbf{x}_{j}$ are the covariates for individual $j, \mathbf{z}_{j}$ are the covariates used to model the variance of the outcome for the heteroskedastic probit model, and $\Phi$ is the standard normal cumulative density function.

fracreg postestimation - Postestimation tools for fracreg

| Postestimation commands | predict |
| :--- | :--- |
| Remarks and examples | Also see |

## Postestimation commands

The following standard postestimation commands are available after fracreg:

| Command | Description |
| :--- | :--- |
| contrast | contrasts and ANOVA-style joint tests of estimates <br> estat ic |
| Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian in- <br> formation criteria (AIC, CAIC, AICc, and BIC) |  |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estat (svy) | postestimation statistics for survey data <br> cataloging estimation results |
| estimates | table of estimation results |
| etable | dynamic forecasts and simulations |
| forecast | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations |
| of coefficients |  |

[^28]
## predict

## Description for predict

predict creates a new variable containing predictions such as conditional means, linear predictions, standard errors, and equation-level scores.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] stub* [if] [in], scores
```

statistic Description

Main
$\mathrm{cm} \quad$ conditional mean; the default
$\mathrm{xb} \quad$ linear prediction
sigma standard deviation of the error term (for het())
stdp standard error of the linear prediction

## Options for predict

$\qquad$ Main
cm , the default, calculates the conditional mean of the outcome.
xb calculates the linear prediction.
sigma calculates the standard deviation of the error term. It is available only when het () is specified. stdp calculates the standard error of the linear prediction.
nooffset is relevant only if you specified offset (varname). It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_{j} \mathbf{b}$ rather than as $\mathbf{x}_{j} \mathbf{b}+$ offset $_{j}$.
scores calculates the equation-level scores. In the case of fracreg probit and fracreg logit, $\partial \ln L / \partial\left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$ is calculated, and if the option het() was specified with fracreg probit, then $\partial \ln L / \partial\left(\mathbf{z}_{j} \gamma\right)$ is also calculated.

## margins

## Description for margins

margins estimates margins of response for conditional means and linear predictions.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [点redict(statistic ...)...] [options]
```

statistic Description
$\mathrm{cm} \quad$ conditional mean; the default
$x b \quad$ linear prediction
sigma standard deviation of the error term (for het())
stdp not allowed with margins
scores not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

## Remarks and examples

Remarks are presented under the following headings:
Obtaining predicted values
Performing hypothesis tests

## Obtaining predicted values

Once you have fit a model using fracreg, you can obtain the conditional mean of the fractional response by using the predict command for both the estimation sample and other samples; see [U] 20 Estimation and postestimation commands and [R] predict.

When you use the fractional probit estimator, fracreg probit, with the option het (), there is an additional statistic available, sigma. With the sigma option, predict calculates the predicted standard deviation, $\sigma_{j}=\exp \left(\mathbf{z}_{j} \gamma\right)$.

## Performing hypothesis tests

## > Example 1: Conditional means

In example 1 of [R] fracreg, we fit a fractional probit model to see how participation rate (prate) in 401(k) plans is affected by the matching rate of employer contributions (mrate). To obtain the predicted conditional means, we use predict and do not specify the default cm option.

```
. use https://www.stata-press.com/data/r18/401k
(Firm-level data on 401k participation)
. fracreg probit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole
Iteration 0: Log pseudolikelihood = -1769.6832
Iteration 1: Log pseudolikelihood = -1675.2763
Iteration 2: Log pseudolikelihood = -1674.6234
Iteration 3: Log pseudolikelihood = -1674.6232
Iteration 4: Log pseudolikelihood = -1674.6232
Fractional probit regression Number of obs = 4,075
Wald chi2(6) = 815.88
Prob > chi2 = 0.0000
Pseudo R2 = 0.0632
```

| prate | Coefficient | Robust |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| std. err. | z | P>\|z| | [95\% conf. interval] |  |  |  |
| mrate | .5859715 | .0387616 | 15.12 | 0.000 | .5100002 | .6619429 |
| ltotemp | -.6102767 | .0615052 | -9.92 | 0.000 | -.7308246 | -.4897288 |
| c.ltotemp\# |  |  |  |  |  |  |
| c.ltotemp | .0313576 | .003975 | 7.89 | 0.000 | .0235667 | .0391484 |
| age | .0273266 | .0031926 | 8.56 | 0.000 | .0210691 | .033584 |
| c.age\#c.age | -.0003159 | .0000875 | -3.61 | 0.000 | -.0004874 | -.0001443 |
| sole |  |  |  |  |  |  |
| Only plan | .0683196 | .0272091 | 2.51 | 0.012 | .0149908 | .1216484 |
| _cons | 3.25991 | .2323929 | 14.03 | 0.000 | 2.804429 | 3.715392 |

```
- predict mpart
(option cm assumed)
```

We can then summarize these conditional mean estimates (cmean) over the population to get the population average conditional mean participation rate in our sample.

```
. summarize mpart
```

| Variable | Obs | Mean | Std. dev. | Min | Max |
| ---: | ---: | ---: | ---: | ---: | ---: |
| mpart | 4,075 | .8405767 | .0828094 | .6251739 | .9964518 |

The average of the conditional mean of participation rate in our sample is $84 \%$ with a range between $62.5 \%$ and $99.6 \%$.

## > Example 2: Average marginal effects

In example 2 of $[\mathrm{R}]$ fracreg, we used the outcome variable and covariates of example 1 but instead of fitting a fractional probit regression, we fit a fractional logit. Using margins, we explore the average marginal effect of mrate on prate for both specifications.

Below, we use margins after fracreg logit with the option post to post the average marginal effects as estimates. We then store our results with the name logit. We do the same with our probit estimates.

| . fracreg logit prate mrate c.ltotemp\#\#c.ltotemp c.age\#\#c.age i.sole, or |  |  |  | c.age\#\#c.age i.sole, or |  |  |

```
. estimates store logit
```

The marginal effects from fracreg logit suggest that a small change in the matching rate of employers can increase participation by more than $14 \%$.

```
. quietly fracreg probit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole
. margins, dydx(mrate) post
Average marginal effects Number of obs = 4,075
Model VCE: Robust
Expression: Conditional mean of prate, predict()
dy/dx wrt: mrate
```

|  | Delta-method |  |  |  |  |  |
| ---: | ---: | ---: | :---: | :---: | :---: | :---: |
|  | dy/dx | std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| mrate | .1335505 | .0087385 | 15.28 | 0.000 | .1164233 | .1506776 |

```
. estimates store probit
```

For the probit model, a change in the matching rate increases participation by more than $13 \%$.
Because we stored our margins results as estimates, we can now produce a table showing both the logit and probit results.
. estimates table logit probit, se

| Variable | logit | probit |
| ---: | :--- | :--- |
| mrate | .14501059 | .13355046 |
|  | .00945578 | .00873852 |

Legend: b/se
As indicated by the standard errors in the table, both average marginal effects are significant. The difference between the two estimates is approximately one percentage point. This relatively small difference is consistent with the intuition that marginal effects obtained from probit and logit conditional means give us analogous results.
> Example 3: Average marginal effects for different levels of participation
We can also use margins to find the expected participation rate for various levels of employer matching. Using our probit model, we obtain the following by typing

```
. quietly fracreg probit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole
. margins, at(mrate=(0(.2)2))
Predictive margins Number of obs = 4,075
Model VCE: Robust
Expression: Conditional mean of prate, predict()
1._at: mrate = 0
2._at: mrate = .2
3._at: mrate = .4
4._at: mrate = . }
5._at: mrate = . 8
6._at: mrate = 1
7._at: mrate = 1.2
8._at: mrate = 1.4
9._at: mrate = 1.6
10._at: mrate = 1.8
11._at: mrate = 2
```

|  | Delta-method <br> std. err. |  |  |  |  | $\mathbf{z}$ |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Margin | P>\|z| | [95\% conf. interval] |  |  |  |
| at |  |  |  |  |  |  |
| 1 | .780858 | .0052738 | 148.06 | 0.000 | .7705216 | .7911944 |

## Title

frontier - Stochastic frontier models

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| References | Also see |  |  |

## Description

frontier fits stochastic production or cost frontier models; the default is a production frontier model. It provides estimators for the parameters of a linear model with a disturbance that is assumed to be a mixture of two components, which have a strictly nonnegative and symmetric distribution, respectively. frontier can fit models in which the nonnegative distribution component (a measurement of inefficiency) is assumed to be from a half-normal, exponential, or truncated-normal distribution. See Kumbhakar and Lovell (2000) for a detailed introduction to frontier analysis.

## Quick start

Cobb-Douglas production frontier model of $\operatorname{lny} 1$ as a function of $\ln x 1$ and $\ln x 2$ frontier lny1 lnx1 lnx2

Same as above, but use exponential instead of half-normal distribution for the inefficiency term frontier lny1 lnx1 lnx2, distribution(exponential)

Include $x 3$ as an explanatory variable in the idiosyncratic error variance function frontier $\operatorname{lny} 1 \ln x 1 \ln x 2$, vhet( $x 3$ )

Same as above, and include $x 4$ as an explanatory variable in the technical inefficiency variance function

```
frontier lny1 lnx1 lnx2, vhet(x3) uhet(x4)
```

Conditional mean model with the mean modeled as a linear function of x3
frontier lny1 lnx1 lnx2, distribution(tnormal) cm(x3)
Cost frontier model of y 2 as a function of $\ln x 1$ and $\ln x 2$
frontier y2 lnx1 lnx2, distribution(tnormal) cost

## Menu

Reporting
level(\#)
nocnsreport
display_options
vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife
explanatory variables for idiosyncratic error variance function; use noconstant to suppress constant term fit cost frontier model; default is production frontier model
set confidence level; default is level(95)
do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

## Maximization

maximize_options
collinear
coeflegend
control the maximization process; seldom used
keep collinear variables
display legend instead of statistics
*vce(robust) and vce(cluster clustvar) may not be specified with distribution(tnormal).
indepvars and varlist may contain factor variables; see [U] 11.4.3 Factor variables.
bootstrap, by, collect, fp, jackknife, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

## Model <br> noconstant; see [R] Estimation options.

distribution (distname) specifies the distribution for the inefficiency term as half-normal (hnormal), exponential, or truncated-normal (tnormal). The default is hnormal.
ufrom (matrix) specifies a $1 \times K$ matrix of untransformed starting values when the distribution is truncated-normal (tnormal). frontier can estimate the parameters of the model by maximizing either the $\log$ likelihood or a transformed log likelihood (see Methods and formulas). frontier automatically transforms the starting values before passing them on to the transformed log likelihood. The matrix must have the same number of columns as there are parameters to estimate.
cm (varlist [, noconstant]) may be used only with distribution(tnormal). Here frontier will fit a conditional mean model in which the mean of the truncated-normal distribution is modeled as a linear function of the set of covariates specified in varlist. Specifying noconstant suppresses the constant in the mean function.

## Model 2

constraints (constraints); see [R] Estimation options.
By default, when fitting the truncated-normal model or the conditional mean model, frontier maximizes a transformed log likelihood. When constraints are applied, frontier will maximize the untransformed $\log$ likelihood with constraints defined in the untransformed metric.
uhet (varlist [, noconstant ]) specifies that the technical inefficiency component is heteroskedastic, with the variance function depending on a linear combination of varlist ${ }_{u}$. Specifying noconstant suppresses the constant term from the variance function. This option may not be specified with distribution(tnormal).
vhet (varlist [, noconstant]) specifies that the idiosyncratic error component is heteroskedastic, with the variance function depending on a linear combination of varlist $t_{v}$. Specifying noconstant suppresses the constant term from the variance function. This option may not be specified with distribution(tnormal).
cost specifies that frontier fit a cost frontier model.

## SE/Robust

vce (vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
vce(robust) and vce(cluster clustvar) may not be specified with distribution(tnormal).

[^29]maximize_options: difficult, technique (algorithm_spec), iterate(\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance (\#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique (bhhh) resets the default vcetype to vce (opg).

The following options are available with frontier but are not shown in the dialog box:
collinear, coeflegend; see [R] Estimation options.

## Remarks and examples

Stochastic production frontier models were introduced by Aigner, Lovell, and Schmidt (1977) and Meeusen and van den Broeck (1977). Since then, stochastic frontier models have become a popular subfield in econometrics. Kumbhakar and Lovell (2000) provide a good introduction.
frontier fits three stochastic frontier models with distinct parameterizations of the inefficiency term and can fit stochastic production or cost frontier models.

Let's review the nature of the stochastic frontier problem. Suppose that a producer has a production function $f\left(\mathbf{z}_{i}, \boldsymbol{\beta}\right)$. In a world without error or inefficiency, the $i$ th firm would produce

$$
q_{i}=f\left(\mathbf{z}_{i}, \boldsymbol{\beta}\right)
$$

Stochastic frontier analysis assumes that each firm potentially produces less than it might due to a degree of inefficiency. Specifically,

$$
q_{i}=f\left(\mathbf{z}_{i}, \boldsymbol{\beta}\right) \xi_{i}
$$

where $\xi_{i}$ is the level of efficiency for firm $i ; \xi_{i}$ must be in the interval $(0,1]$. If $\xi_{i}=1$, the firm is achieving the optimal output with the technology embodied in the production function $f\left(\mathbf{z}_{i}, \boldsymbol{\beta}\right)$. When $\xi_{i}<1$, the firm is not making the most of the inputs $\mathbf{z}_{i}$ given the technology embodied in the production function $f\left(\mathbf{z}_{i}, \boldsymbol{\beta}\right)$. Because the output is assumed to be strictly positive (that is, $q_{i}>0$ ), the degree of technical efficiency is assumed to be strictly positive (that is, $\xi_{i}>0$ ).

Output is also assumed to be subject to random shocks, implying that

$$
q_{i}=f\left(\mathbf{z}_{i}, \boldsymbol{\beta}\right) \xi_{i} \exp \left(v_{i}\right)
$$

Taking the natural $\log$ of both sides yields

$$
\ln \left(q_{i}\right)=\ln \left\{f\left(\mathbf{z}_{i}, \boldsymbol{\beta}\right)\right\}+\ln \left(\xi_{i}\right)+v_{i}
$$

Assuming that there are $k$ inputs and that the production function is linear in logs, defining $u_{i}=-\ln \left(\xi_{i}\right)$ yields

$$
\begin{equation*}
\ln \left(q_{i}\right)=\beta_{0}+\sum_{j=1}^{k} \beta_{j} \ln \left(z_{j i}\right)+v_{i}-u_{i} \tag{1}
\end{equation*}
$$

Because $u_{i}$ is subtracted from $\ln \left(q_{i}\right)$, restricting $u_{i} \geq 0$ implies that $0<\xi_{i} \leq 1$, as specified above.

Kumbhakar and Lovell (2000) provide a detailed version of the above derivation, and they show that performing an analogous derivation in the dual cost function problem allows us to specify the problem as

$$
\begin{equation*}
\ln \left(c_{i}\right)=\beta_{0}+\beta_{q} \ln \left(q_{i}\right)+\sum_{j=1}^{k} \beta_{j} \ln \left(p_{j i}\right)+v_{i}+u_{i} \tag{2}
\end{equation*}
$$

where $q_{i}$ is output, $z_{j i}$ are input quantities, $c_{i}$ is cost, and the $p_{j i}$ are input prices.
Intuitively, the inefficiency effect is required to lower output or raise expenditure, depending on the specification.

## - Technical note

The model that frontier actually fits is of the form

$$
y_{i}=\beta_{0}+\sum_{j=1}^{k} \beta_{j} x_{j i}+v_{i}-s u_{i}
$$

where

$$
s=\left\{\begin{aligned}
1, & \text { for production functions } \\
-1, & \text { for cost functions }
\end{aligned}\right.
$$

so, in the context of the discussion above, $y_{i}=\ln \left(q_{i}\right)$, and $x_{j i}=\ln \left(z_{j i}\right)$ for a production function; and for a cost function, $y_{i}=\ln \left(c_{i}\right)$, and the $x_{j i}$ are the $\ln \left(p_{j i}\right)$ and $\ln \left(q_{i}\right)$. You must take the natural logarithm of the data before fitting a stochastic frontier production or cost model. frontier performs no transformations on the data.

Different specifications of the $u_{i}$ and the $v_{i}$ terms give rise to distinct models. frontier provides estimators for the parameters of three basic models in which the idiosyncratic component, $v_{i}$, is assumed to be independently $N\left(0, \sigma_{v}\right)$ distributed over the observations. The basic models differ in their specification of the inefficiency term, $u_{i}$, as follows:
exponential: the $u_{i}$ are independently exponentially distributed with variance $\sigma_{u}^{2}$ hnormal: the $u_{i}$ are independently half-normally $N^{+}\left(0, \sigma_{u}^{2}\right)$ distributed tnormal: the $u_{i}$ are independently $N^{+}\left(\mu, \sigma_{u}^{2}\right)$ distributed with truncation point at 0
For half-normal or exponential distributions, frontier can fit models with heteroskedastic error components, conditional on a set of covariates. For a truncated-normal distribution, frontier can also fit a conditional mean model in which the mean is modeled as a linear function of a set of covariates.

## > Example 1: The half-normal and the exponential models

For our first example, we demonstrate the half-normal and exponential models by reproducing a study found in Greene (2003, 505), which uses data originally published in Zellner and Revankar (1969). In this study of the transportation equipment manufacturing industry, observations on value added, capital, and labor are used to estimate a Cobb-Douglas production function. The variable lnv is the log-transformed value added, lnk is the log-transformed capital, and $\operatorname{lnl}$ is the log-transformed labor. OLS estimates are compared with those from stochastic frontier models using both the half-normal and exponential distribution for the inefficiency term.

The parameter estimates and the estimates of the inefficiency terms closely match those published in Greene (2003, 505), but the standard errors of the parameter estimates are estimated differently (see the technical note below).

The output from frontier includes estimates of the standard deviations of the two error components, $\sigma_{v}$ and $\sigma_{u}$, which are labeled sigma_v and sigma_u, respectively. In the log likelihood, they are parameterized as $\ln \sigma_{v}^{2}$ and $\ln \sigma_{u}^{2}$, and these estimates are labeled $/ \ln s i g 2 \mathrm{v}$ and $/ \operatorname{lnsig} 2 \mathrm{u}$ in the output. frontier also reports two other useful parameterizations. The estimate of the total error variance, $\sigma_{S}^{2}=\sigma_{v}^{2}+\sigma_{u}^{2}$, is labeled sigma2, and the estimate of the ratio of the standard deviation of the inefficiency component to the standard deviation of the idiosyncratic component, $\lambda=\sigma_{u} / \sigma_{v}$, is labeled lambda.

At the bottom of the output, frontier reports the results of a test that there is no technical inefficiency component in the model. This is a test of the null hypothesis $H_{0}: \sigma_{u}^{2}=0$ against the alternative hypotheses $H_{1}: \sigma_{u}^{2}>0$. If the null hypothesis is true, the stochastic frontier model reduces to an OLS model with normal errors. However, because the test lies on the boundary of the parameter space of $\sigma_{u}^{2}$, the standard likelihood-ratio test is not valid, and a one-sided generalized likelihood-ratio test must be constructed; see Gutierrez, Carter, and Drukker (2001). For this example, the output shows LR $=0.43$ with a $p$-value of 0.256 for the half-normal model and $\mathrm{LR}=1.21$ with a $p$-value of 0.135 for the exponential model. There are several possible reasons for the failure to reject the null hypothesis, but the fact that the test is based on an asymptotic distribution and the sample size was 25 is certainly a leading candidate among those possibilities.

## Technical note

frontier maximizes the log-likelihood function of a stochastic frontier model by using the Newton-Raphson method, and the estimated variance-covariance matrix is calculated as the inverse of the negative Hessian (matrix of second partial derivatives); see $[\mathrm{R}] \mathrm{ml}$. When comparing the results with those published using other software, be aware of the difference in the optimization methods, which may result in different, yet asymptotically equivalent, variance estimates.
> Example 2: Models with heteroskedasticity
Often the error terms may not have constant variance. frontier allows you to model heteroskedasticity in either error term as a linear function of a set of covariates. The variance of either the technical inefficiency or the idiosyncratic component may be modeled as

$$
\sigma_{i}^{2}=\exp \left(\mathbf{w}_{i} \boldsymbol{\delta}\right)
$$

The default constant included in $\mathbf{w}_{i}$ may be suppressed by appending a noconstant option to the list of covariates. Also, you can simultaneously specify covariates for both $\sigma_{u_{i}}$ and $\sigma_{v_{i}}$.

In this example, we use a sample of 756 observations of fictional firms producing a manufactured good by using capital and labor. The firms are hypothesized to use a constant returns-to-scale technology, but the sizes of the firms differ. Believing that this size variation will introduce heteroskedasticity into the idiosyncratic error term, we estimate the parameters of a Cobb-Douglas production function. To do this, we use a conditional heteroskedastic half-normal model, with the size of the firm as an explanatory variable in the variance function for the idiosyncratic error. We also perform a test of the hypothesis that the firms use a constant returns-to-scale technology.

. test _b[lnlabor] + _b[lncapital] = 1
    ( 1) [lnoutput]lnlabor + [lnoutput]lncapital = 1
    chi2( 1) = 0.03
    Prob > chi2 = 0.8622
```

The output above indicates that the variance of the idiosyncratic error term is a function of firm size. Also, we failed to reject the hypothesis that the firms use a constant returns-to-scale technology.

## Technical note

In small samples, the conditional heteroskedastic estimators will lack precision for the variance parameters and may fail to converge altogether.
> Example 3: The truncated-normal model
Let's turn our attention to the truncated-normal model. Once again, we will use fictional data. For this example, we have 1,231 observations on the quantity of output, the total cost of production for each firm, the prices that each firm paid for labor and capital services, and a categorical variable measuring the quality of each firm's management. After taking the natural logarithm of the costs (lncost), prices (lnp_k and lnp_l), and output (lnout), we fit a stochastic cost frontier model and specify the distribution for the inefficiency term to be truncated normal.

```

HO: No inefficiency component: z = 5.595
Prob >= z = 0.0000

In addition to the coefficients, the output reports estimates for several parameters. sigma_v2 is the estimate of $\sigma_{v}^{2}$. sigma_u2 is the estimate of $\sigma_{u}^{2}$. gamma is the estimate of $\gamma=\sigma_{u}^{2} / \sigma_{S}^{2}$. sigma2 is the estimate of $\sigma_{S}^{2}=\sigma_{v}^{2}+\sigma_{u}^{2}$. Because $\gamma$ must be between 0 and 1 , the optimization is parameterized in terms of the logit of $\gamma$, and this estimate is reported as lgtgamma. Because $\sigma_{S}^{2}$ must be positive, the optimization is parameterized in terms of $\ln \left(\sigma_{S}^{2}\right)$, whose estimate is reported as lnsigma2. Finally, mu is the estimate of $\mu$, the mean of the truncated-normal distribution.

In the output above, the generalized log-likelihood test for the presence of the inefficiency term has been replaced with a test based on the third moment of the OLS residuals. When $\mu=0$ and $\sigma_{u}=0$, the truncated-normal model reduces to a linear regression model with normally distributed errors. However, the distribution of the test statistic under the null hypothesis is not well established, because it becomes impossible to evaluate the $\log$ likelihood as $\sigma_{u}$ approaches zero, prohibiting the use of the likelihood-ratio test.

However, Coelli (1995) noted that the presence of an inefficiency term would negatively skew the residuals from an OLS regression. By identifying negative skewness in the residuals with the presence of an inefficiency term, Coelli derived a one-sided test for the presence of the inefficiency term. The results of this test are given at the bottom of the output. For this example, the null hypothesis of no inefficiency component is rejected.

In the example below, we fit a truncated model and detect a statistically significant inefficiency term in the model. We might question whether the inefficiency term is identically distributed over all firms or whether there might be heterogeneity across firms. frontier provides an extension to the truncated normal model by allowing the mean of the inefficiency term to be modeled as a linear function of a set of covariates. In our dataset, we have a categorical variable that measures the quality of a firm's management. We refit the model, including the cm () option, specifying a set of
binary indicator variables representing the different categories of the quality-measurement variable as covariates.

The conditional mean model was developed in the context of panel-data estimators, and we can apply frontier's conditional mean model to panel data.

## Stored results

frontier stores the following in e():

In addition to the above, the following is stored in r() :
Matrices
$r$ (table)
matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in $r()$ are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

Consider an equation of the form

$$
y_{i}=\mathbf{x}_{i} \boldsymbol{\beta}+v_{i}-s u_{i}
$$

where $y_{i}$ is the dependent variable, $\mathbf{x}_{i}$ is a $1 \times k$ vector of observations on the independent variables included as indent covariates, $\boldsymbol{\beta}$ is a $k \times 1$ vector of coefficients, and

$$
s=\left\{\begin{aligned}
1, & \text { for production functions } \\
-1, & \text { for cost functions }
\end{aligned}\right.
$$

The log-likelihood functions are as follows.
Normal/half-normal model:

$$
\ln L=\sum_{i=1}^{N}\left\{\frac{1}{2} \ln \left(\frac{2}{\pi}\right)-\ln \sigma_{S}+\ln \Phi\left(-\frac{s \epsilon_{i} \lambda}{\sigma_{S}}\right)-\frac{\epsilon_{i}^{2}}{2 \sigma_{S}^{2}}\right\}
$$

Normal/exponential model:

$$
\ln L=\sum_{i=1}^{N}\left\{-\ln \sigma_{u}+\frac{\sigma_{v}^{2}}{2 \sigma_{u}^{2}}+\ln \Phi\left(\frac{-s \epsilon_{i}-\frac{\sigma_{v}^{2}}{\sigma_{u}}}{\sigma_{v}}\right)+\frac{s \epsilon_{i}}{\sigma_{u}}\right\}
$$

Normal/truncated-normal model:

$$
\begin{aligned}
\ln L= & \sum_{i=1}^{N}\left\{-\frac{1}{2} \ln (2 \pi)-\ln \sigma_{S}-\ln \Phi\left(\frac{\mu}{\sigma_{S} \sqrt{\gamma}}\right)\right. \\
& \left.+\ln \Phi\left[\frac{(1-\gamma) \mu-s \gamma \epsilon_{i}}{\left\{\sigma_{S}^{2} \gamma(1-\gamma)\right\}^{1 / 2}}\right]-\frac{1}{2}\left(\frac{\epsilon_{i}+s \mu}{\sigma_{S}}\right)^{2}\right\}
\end{aligned}
$$

where $\sigma_{S}=\left(\sigma_{u}^{2}+\sigma_{v}^{2}\right)^{1 / 2}, \lambda=\sigma_{u} / \sigma_{v}, \gamma=\sigma_{u}^{2} / \sigma_{S}^{2}, \epsilon_{i}=y_{i}-\mathbf{x}_{i} \boldsymbol{\beta}$, and $\Phi()$ is the cumulative distribution function of the standard normal distribution.

To obtain estimation for $u_{i}$, you can use either the mean or the mode of the conditional distribution $f(u \mid \epsilon)$.

$$
\begin{aligned}
& E\left(u_{i} \mid \epsilon_{i}\right)=\mu_{* i}+\sigma_{*}\left\{\frac{\phi\left(-\mu_{* i} / \sigma_{*}\right)}{\Phi\left(\mu_{* i} / \sigma_{*}\right)}\right\} \\
& M\left(u_{i} \mid \epsilon_{i}\right)= \begin{cases}\mu_{* i} & \text { if } \mu_{* i} \geq 0 \\
0 & \text { otherwise }\end{cases}
\end{aligned}
$$

Then, the technical efficiency $(s=1)$ or cost efficiency $(s=-1)$ will be estimated by

$$
\begin{aligned}
E_{i} & =E\left\{\exp \left(-s u_{i}\right) \mid \epsilon_{i}\right\} \\
& =\left\{\frac{1-\Phi\left(s \sigma_{*}-\mu_{* i} / \sigma_{*}\right)}{1-\Phi\left(-\mu_{* i} / \sigma_{*}\right)}\right\} \exp \left(-s \mu_{* i}+\frac{1}{2} \sigma_{*}^{2}\right)
\end{aligned}
$$

where $\mu_{* i}$ and $\sigma_{*}$ are defined for the normal/half-normal model as

$$
\begin{aligned}
\mu_{* i} & =-s \epsilon_{i} \sigma_{u}^{2} / \sigma_{S}^{2} \\
\sigma_{*} & =\sigma_{u} \sigma_{v} / \sigma_{S}
\end{aligned}
$$

for the normal/exponential model as

$$
\begin{aligned}
\mu_{* i} & =-s \epsilon_{i}-\sigma_{v}^{2} / \sigma_{u} \\
\sigma_{*} & =\sigma_{v}
\end{aligned}
$$

and for the normal/truncated-normal model as

$$
\begin{aligned}
\mu_{* i} & =\frac{-s \epsilon_{i} \sigma_{u}^{2}+\mu \sigma_{v}^{2}}{\sigma_{S}^{2}} \\
\sigma_{*} & =\sigma_{u} \sigma_{v} / \sigma_{S}
\end{aligned}
$$

In the half-normal and exponential models, when heteroskedasticity is assumed, the standard deviations, $\sigma_{u}$ or $\sigma_{v}$, will be replaced in the above equations by

$$
\sigma_{i}^{2}=\exp \left(\mathbf{w}_{i} \boldsymbol{\delta}\right)
$$

where $\mathbf{w}$ is the vector of explanatory variables in the variance function.
In the conditional mean model, the mean parameter of the truncated normal distribution, $\mu$, is modeled as a linear combination of the set of covariates, $\mathbf{w}$.

$$
\mu=\mathbf{w}_{i} \boldsymbol{\delta}
$$

Therefore, the log-likelihood function can be rewritten as

$$
\begin{aligned}
\ln L= & \sum_{i=1}^{N}\left[-\frac{1}{2} \ln (2 \pi)-\ln \sigma_{S}-\ln \Phi\left(\frac{\mathbf{w}_{i} \boldsymbol{\delta}}{\sqrt{\sigma_{S}^{2} \gamma}}\right)\right. \\
& \left.+\ln \Phi\left\{\frac{(1-\gamma) \mathbf{w}_{i} \boldsymbol{\delta}-s \gamma \epsilon_{i}}{\sqrt{\sigma_{S}^{2} \gamma(1-\gamma)}}\right\}-\frac{1}{2}\left(\frac{\epsilon_{i}+s \mathbf{w}_{i} \boldsymbol{\delta}}{\sigma_{S}}\right)^{2}\right]
\end{aligned}
$$

The $z$ test reported in the output of the truncated-normal model is a third-moment test developed by Coelli (1995) as an extension of a test previously developed by Pagan and Hall (1983). Coelli shows that under the null of normally distributed errors, the statistic

$$
z=\frac{m_{3}}{\left(\frac{6 m_{2}^{3}}{N}\right)^{1 / 2}}
$$

has a standard normal distribution, where $m_{3}$ is the third moment from the OLS regression. Because the residuals are either negatively skewed (production function) or positively skewed (cost function), a one-sided $p$-value is used.

| :--- | :--- |
| Reference | Also see |

## Postestimation commands

The following postestimation commands are available after frontier:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| linktest | link test for model specification |
| lrtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | predictions and their SEs, technical efficiency, etc. |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

## predict

## Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, and estimates of technical efficiency.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
predict [type]stub* [if] [in], scores
```

statistic Description

## Main

$\mathrm{xb} \quad$ linear prediction; the default
stdp standard error of the prediction
$\mathrm{u} \quad$ estimates of minus the natural $\log$ of the technical efficiency via $E\left(u_{i} \mid \epsilon_{i}\right)$
m
te estimates of minus the natural $\log$ of the technical efficiency via $M\left(u_{i} \mid \epsilon_{i}\right)$ estimates of the technical efficiency via $E\left\{\exp \left(-s u_{i}\right) \mid \epsilon_{i}\right\}$
$s=\left\{\begin{aligned} 1, & \text { for production functions } \\ -1, & \text { for cost functions }\end{aligned}\right.$
These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

## Options for predict

Main
xb , the default, calculates the linear prediction.
stdp calculates the standard error of the linear prediction.
u produces estimates of minus the natural $\log$ of the technical efficiency via $E\left(u_{i} \mid \epsilon_{i}\right)$.
m produces estimates of minus the natural $\log$ of the technical efficiency via $M\left(u_{i} \mid \epsilon_{i}\right)$. te produces estimates of the technical efficiency via $E\left\{\exp \left(-s u_{i}\right) \mid \epsilon_{i}\right\}$.
scores calculates equation-level score variables.
The first new variable will contain $\partial \ln L / \partial\left(\mathbf{x}_{i} \boldsymbol{\beta}\right)$.
The second new variable will contain $\partial \ln L / \partial(\ln s i g 2 v)$.
The third new variable will contain $\partial \ln L / \partial(\operatorname{lnsig} 2 \mathrm{u})$.
scores may not be specified after estimation with option distribution(tnormal).

## margins

## Description for margins

margins estimates margins of response for linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [options]
```

statistic
Description
xb
linear prediction; the default
stdp not allowed with margins
u not allowed with margins
m not allowed with margins
te not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b). For the full syntax, see [R] margins.

## Remarks and examples

> Example 1
In example 2 of $[\mathrm{R}]$ frontier, we modeled heteroskedasticity by specifying the vhet () option. We would like to compare the predicted efficiency in that case with respect to a model specification without accounting for the presence of heteroskedasticity in the error term. Kumbhakar and Lovell (2000, 117) show that failing to account for heteroskedasticity associated with firm size may lead to bias in the estimation of the technical efficiency. By incorrectly assuming homoskedasticity, the estimates for relatively small firms would be biased upward, while the estimates for relatively large firms would be biased downward. Let's refit the model and use the te option of predict:

```
. use https://www.stata-press.com/data/r18/frontier1
. frontier lnoutput lnlabor lncapital, vhet(size)
    (output omitted)
. predict te_vhet, te
```

Next, we fit the model assuming homoskedasticity and then again predict the technical efficiency with the te option of predict:

```
. frontier lnoutput lnlabor lncapital
    (output omitted)
    predict te, te
```

The graph below shows the estimates for technical efficiency for the smaller and larger firms. The technical efficiency tends to be smaller for smaller firms when the model specification accounts for the presence of heteroskedasticity, whereas the predictions for the technical efficiency tends to be smaller for larger firms assuming homoskedasticity. These results agree with the theoretical statement in Kumbhakar and Lovell (2000) because the firm size was actually relevant to model heteroskedasticity in the idiosyncratic component of the error term.

Predicted technical efficiency for smaller and larger firms

## > Example 2

We also test in example 2 of $[R]$ frontier whether the firms use constant returns to scale. We can use lincom as an alternative to perform an equivalent test based on the normal distribution.

```
. use https://www.stata-press.com/data/r18/frontier1, clear
. frontier lnoutput lnlabor lncapital, vhet(size)
    (output omitted)
. lincom _b[lnlabor] + _b[lncapital]-1
( 1) [lnoutput]lnlabor + [lnoutput]lncapital = 1
```

| lnoutput | Coefficient | Std. err. | $z$ | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| ---: | ---: | ---: | :---: | ---: | ---: | ---: |
| $(1)$ | .1022278 | .5888511 | 0.17 | 0.862 | -1.051899 | 1.256355 |

The $p$-value is exactly the same as the one we obtained with the test command in example 2 of $[R]$ frontier. However, notice that by using lincom, we obtained an estimate of the deviation from the constant returns-to-scale assumption, which is not significantly different from zero in this case.

## Title

fvrevar - Factor-variables operator programming command

| Description | Quick start | Syntax | Options |
| :--- | :--- | :--- | :--- |
| Remarks and examples | Stored results | Also see |  |

## Description

fvrevar creates a variable list that includes equivalent, temporary variables in place of the factor variables, interactions, or time-series-operated variables in varlist. The resulting variable list can be used by commands that do not otherwise support factor variables or time-series-operated variables. The resulting list also could be used in a program to speed execution at the cost of using more memory.

## Quick start

Create temporary indicator variables for the levels of categorical variable a and store names in r(varlist)
fvrevar i.a
Create temporary variables corresponding to the levels of $a, b$, and their interaction
fvrevar i.a\#\#i.b
Same as above, and create a temporary variable for the lag of x using tsset data fvrevar i.a\#\#i.b L.x

Return the list of unoperated variables ( $\mathrm{a}, \mathrm{b}$, and x ) in r (varlist)
fvrevar i.a\#\#i.b L.x, list
Create new variables $\mathrm{a} \_1, \mathrm{a} \_2, \ldots$, corresponding to the levels of a
fvrevar i.a, stub(a_)
Create new variables $a b \_1, a b \_2, \ldots$, corresponding to the levels of the interaction between $a \operatorname{and} b$ fvrevar i.a\#i.b, stub(ab_)

## Syntax

```
fvrevar [varlist][if][in] [, substitute tsonly list stub(stub)]
```

You must tsset your data before using fvrevar if varlist contains time-series operators; see [TS] tsset. collect is allowed; see [U] 11.1.10 Prefix commands.

## Options

substitute specifies that equivalent, temporary variables be substituted for any factor variables, interactions, or time-series-operated variables in varlist. substitute is the default action taken by fvrevar; you do not need to specify the option.
tsonly specifies that equivalent, temporary variables be substituted for only the time-series-operated variables in varlist.
list specifies that all factor-variable operators and time-series operators be removed from varlist and the resulting list of base variables be returned in $r$ (varlist). No new variables are created with this option.
stub (stub) specifies that fvrevar generate named variables instead of temporary variables. The new variables will be named stub\#.

## Remarks and examples

fvrevar might create no new variables, one new variable, or many new variables, depending on the number of factor variables, interactions, and time-series operators appearing in varlist. Any new variables created are temporary. The new, equivalent varlist is returned in $r$ (varlist). The new varlist corresponds one to one with the original varlist.
$>$ Example 1
Typing

```
. use https://www.stata-press.com/data/r18/auto2
. fvrevar i.rep78 mpg turn
```

creates five temporary variables corresponding to the levels of rep78. No new variables are created for variables mpg and turn because they do not contain factor-variable or time-series operators.

The resulting variable list is

```
. display "'r(varlist)'"
__000000 __000001 __000002 __000003 __000004 mpg turn
```

(Your temporary variable names may be different, but that is of no consequence.)
Temporary variables automatically vanish when the program concludes.

## > Example 2

Suppose we want to create temporary variables for specific levels of a factor variable. To do this, we can use the parenthesis notation of factor-variable syntax.

```
. fvrevar i (2,3)bn.rep78 mpg
```

creates two temporary variables corresponding to levels 2 and 3 of rep78. Notice that we specified that neither level 2 nor 3 be set as the base level by using the bn notation. If we did not specify bn, level 2 would have been treated as the base level.

The resulting variable list is

```
. display "'r(varlist)'"
__000005 __000002 mpg
```

We can see the results by listing the new variables alongside the original value of rep78.

```
. list rep78 'r(varlist)' in 1/5
```

| rep78 | _-000005 | _-000002 | mpg |
| ---: | ---: | ---: | ---: |
| Average | 0 | 1 | 22 |
| Average | 0 | 1 | 17 |
| $\cdot$ | . | . | 22 |
| Average | 0 | 1 | 20 |
| Good | 0 | 0 | 15 |

If we had needed only the base-variable names, we could have specified

```
. fvrevar i(2,3)bn.rep78 mpg, list
. display "'r(varlist)'"
mpg rep78
```

The order of the list will probably differ from that of the original list; base variables are listed only once.

## > Example 3

Now let's assume we have a varlist containing both an interaction and time-series-operated variables. If we want to create temporary variables for the entire equivalent varlist, we can specify fvrevar with no options.

```
. generate t = _n
. tsset t
    time variable: t, 1 to 74
        delta: 1 unit
. fvrevar c.turn#i(2,3).rep78 L.mpg
```

The resulting variable list is

```
. display "'r(varlist)'"
__000006 __000007 __000008
```

If we want to create temporary variables only for the time-series-operated variables, we can specify the tsonly option.

```
. fvrevar c.turn#i(2,3).rep78 L.mpg, tsonly
```

The resulting variable list is
. display "'r(varlist)'"
2.rep78\#c.turn 3.rep78\#c.turn __000008

Notice that fvrevar returned the expanded factor-variable list with the tsonly option.

- Technical note
fvrevar, substitute avoids creating duplicate variables. Consider
. fvrevar i.rep78 turn mpg i.rep78
i.rep78 appears twice in the varlist. fvrevar will create only one set of new variables for the five levels of rep78 and will use these new variables once in the resulting r(varlist). Moreover, fvrevar will do this even across multiple calls:
. fvrevar i.rep78 turn mpg
. fvrevar i.rep78
i.rep78 appears in two separate calls. At the first call, fvrevar creates five temporary variables corresponding to the five levels of rep78. At the second call, fvrevar remembers what it has done and uses the same temporary variables for i.rep78.

## Stored results

fvrevar stores the following in $r()$ :
Macros
$r$ (varlist) the modified variable list or list of base-variable names

## Title

fvset - Declare factor-variable settings

Description Quick start Syntax Options Remarks and examples
Stored results

## Description

fvset base, fvset design, and fvset clear manage factor-variable settings, which identify the base level and specify how to accumulate statistics over levels. fvset base declares the base level for each specified variable; the default for factor variables without a declared base level is the lowest value. fvset design specifies how the margins command is to accumulate over the levels of a factor variable. fvset clear removes factor-variable settings for each variable in varlist. fvset clear _all removes all factor-variable settings from all variables.
fvset report reports the current factor-variable settings for each variable in varlist. fvset without arguments is a synonym for fvset report.

## Quick start

Set the base category of categorical variable a1 to 3
fvset base 3 a1
Set the base category of a2, a3, and a4 to each variable's largest observed value
fvset base last a2 a3 a4
Set the base category of a5 to the most frequent category
fvset base frequent a5
Set a6 to have no base category
fvset base none a6
Restore the default base category (first) for a5
fvset base default a5
Specify that margins should treat a2 as though it is balanced
fvset design asbalanced a2
Clear factor-variable settings for a2 to a4
fvset clear a2-a4
List factor-variable settings for all factor variables
fvset report

## Syntax

Declare base settings
fvset base base_spec varlist

Declare design settings
fvset design design_spec varlist

Clear the current settings
fvset clear varlist

Report the current settings
fvset report [varlist] [, base(base_spec) design(design_spec)]

| base_spec | Description |
| :--- | :--- |
| default | default base |
| first | lowest level value; the default |
| last | highest level value |
| frequent | most frequent level value |
| none | no base |
| $\#$ | nonnegative integer value |

design_spec Description
default default design
asbalanced accumulate using $1 / k, k=$ number of levels
asobserved accumulate using observed relative frequencies; the default
collect is allowed; see [U] 11.1.10 Prefix commands.

## Options

base (base_spec) restricts fvset report to report only the factor-variable settings for variables with the specified base_spec.
design (design_spec) restricts fvset report to report only the factor-variable settings for variables with the specified design_spec.

## Remarks and examples

## - Example 1

Using auto2.dta, we include factor variable i.rep78 in a regression:

```
. use https://www.stata-press.com/data/r18/auto2
(1978 automobile data)
. regress mpg i.rep78, baselevels
```

| Source | SS | df | MS |
| ---: | :---: | ---: | :---: |
| Model | 549.415777 | 4 | 137.353944 |
| Residual | 1790.78712 | 64 | 27.9810488 |
| Total | 2340.2029 | 68 | 34.4147485 |

| Number of obs | $=$ | 69 |
| :--- | :--- | ---: |
| $\mathrm{~F}(4,64)$ | $=$ | 4.91 |
| Prob $>$ F | $=$ | 0.0016 |
| R-squared | $=$ | 0.2348 |
| Adj R-squared | $=$ | 0.1869 |
| Root MSE | $=$ | 5.2897 |

| mpg | Coefficient | Std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :--- | :---: | :---: | :---: | :---: |
| rep78 |  |  |  |  |  |  |
| Poor | 0 | (base) |  |  |  |  |
| Fair | -1.875 | 4.181884 | -0.45 | 0.655 | -10.22927 | 6.479274 |
| Average | -1.566667 | 3.863059 | -0.41 | 0.686 | -9.284014 | 6.150681 |

| _cons |  |  |  | 28.47229 |  |  |

We specified the baselevels option so that the base level would be included in the output. By default, the first level is the base level. We can change the base level to 2 :
. fvset base 2 rep78
. regress mpg i.rep78, baselevels

| Source | SS | df | MS |
| ---: | :---: | ---: | :---: |
| Model | 549.415777 | 4 | 137.353944 |
| Residual | 1790.78712 | 64 | 27.9810488 |
| Total | 2340.2029 | 68 | 34.4147485 |

| Number of obs | $=$ | 69 |

| Excellent | 27.36364 | 1.594908 | 17.16 | 0.000 | 24.17744 | 30.54983 |

## Example 2

By default, margins assumes that factor variables are to be treated asobserved and accumulates a margin by using the observed relative frequencies of the factor levels or the sum of the weights if weights have been specified.

| Source | SS | df | MS | Number of obs F (1, 72) |  | = | 74 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Model | 378.153515 | 1 | $378.153515$ |  | Prob > F |  | 0.0005 |
| Residual | 2065.30594 | 72 | 28.6848048 | $R$-squared <br> Adj R-squared |  |  | 0.1548 |
|  |  |  |  |  |  |  | 0.1430 |
| Total | 2443.45946 | 73 | 33.4720474 | Root MSE |  | = | 5.3558 |
| mpg | Coefficient | Std. err. | t | $P>\|t\|$ | tl [95\% con |  | interval] |
| foreign |  |  |  |  |  |  |  |
| Foreign | 4.945804 | 1.362162 | 3.63 | 0.001 | 012.230384 |  | 7.661225 |
| _cons | 19.82692 | . 7427186 | 26.70 | 0.000 | 0018.34634 |  | 21.30751 |

. margins
Predictive margins $\quad$ Number of obs $=74$
Model VCE: OLS
Expression: Linear prediction, predict()

|  | Delta-method |  |  |  |  |  |
| :--- | ---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Margin | std. err. | t | $\mathrm{P}>\mid \mathrm{tI}$ | [95\% conf. interval] |  |
| _cons | 21.2973 | .6226014 | 34.21 | 0.000 | 20.05616 | 22.53843 |

Let's set foreign to always accumulate using equal relative frequencies:

```
. fvset design asbalanced foreign
```

. regress mpg i.foreign

| Source | SS | df | MS | Number of obs | = | 74 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $\mathrm{F}(1,72)$ | = | 13.18 |
| Model | 378.153515 | 1 | 378.153515 | Prob > F | = | 0.0005 |
| Residual | 2065.30594 | 72 | 28.6848048 | R -squared | = | 0.1548 |
|  |  |  |  | Adj R-squared | = | 0.1430 |
| Total | 2443.45946 | 73 | 33.4720474 | Root MSE | = | 5.3558 |

| mpg | Coefficient | Std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| ---: | ---: | :--- | ---: | :--- | ---: | :--- |
| foreign |  |  |  |  |  |  |
| Foreign | 4.945804 | 1.362162 | 3.63 | 0.001 | 2.230384 | 7.661225 |
| _cons | 19.82692 | .7427186 | 26.70 | 0.000 | 18.34634 | 21.30751 |

. margins
Adjusted predictions $\quad$ Number of obs $=74$
Model VCE: OLS
Expression: Linear prediction, predict()
At: foreign (asbalanced)

|  | Delta-method |  |  |  |  |  |
| :--- | ---: | :---: | :---: | :---: | :---: | :---: |
|  | Margin | std. err. | $t$ | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| _cons | 22.29983 | .6810811 | 32.74 | 0.000 | 20.94211 | 23.65754 |

Suppose that we issued the fvset design command earlier in our session and that we cannot remember which variables we set as asbalanced. We can retrieve this information by using the fvset report command:

- fvset report, design(asbalanced)

| Variable | Base | Design |
| :--- | :--- | :--- |
| foreign |  | asbalanced |

## - Technical note

margins is aware of a factor variable's design setting only through the estimation results it is working with. The design setting is stored by the estimation command; thus changing the design setting between the estimation command and margins will have no effect. For example, the output from the following two calls to margins yields the same results:

|  | Delta-method |  |  |  |  |  |
| ---: | ---: | :---: | :---: | :---: | :---: | :---: |
|  | Margin | std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| _cons | 21.2973 | .6226014 | 34.21 | 0.000 | 20.05616 | 22.53843 |

```
. fvset design asbalanced foreign
. margins
Predictive margins Number of obs = 74
Model VCE: OLS
Expression: Linear prediction, predict()
```

|  | Delta-method |  |  |  |  |  |
| :--- | ---: | :---: | :---: | :---: | :---: | :---: |
|  | Margin | std. err. | t | $\mathrm{P}>\|\mathrm{t}\|$ | [95\% conf. interval] |  |
| _cons | 21.2973 | .6226014 | 34.21 | 0.000 | 20.05616 | 22.53843 |

## Stored results

fvset stores the following in $r()$ :
Macros

```
r(varlist) varlist
    r(baselist) base setting for each variable in varlist
    r(designlist) design setting for each variable in varlist
```

## Title

gllamm - Generalized linear and latent mixed models
Description Remarks and examples References Also see

## Description

GLLAMM stands for generalized linear latent and mixed models, and gllamm is a Stata command for fitting such models written by Sophia Rabe-Hesketh (University of California-Berkeley) as part of joint work with Anders Skrondal (Norwegian Institute of Public Health) and Andrew Pickles (King's College London).

## Remarks and examples

Generalized linear latent and mixed models are a class of multilevel latent variable models, where a latent variable is a factor or a random effect (intercept or coefficient), or a disturbance (residual). The gllamm command for fitting such models is not an official command of Stata; it has been independently developed by highly regarded authors and is itself highly regarded. You can learn more about gllamm by visiting http://www.gllamm.org.
gllamm is available from the Statistical Software Components (SSC) Archive. To install, type
. ssc describe gllamm
. ssc install gllamm
If you later wish to uninstall gllamm, type ado uninstall gllamm.

## Title

glm - Generalized linear models

| Description | Quick start | Menu | Syntax |
| :--- | :--- | :--- | :--- |
| Options | Remarks and examples | Stored results | Methods and formulas |
| Acknowledgments | References | Also see |  |

## Description

glm fits generalized linear models. It can fit models by using either IRLS (maximum quasilikelihood) or Newton-Raphson (maximum likelihood) optimization, which is the default.

See [U] 27 Overview of Stata estimation commands for a description of all of Stata's estimation commands, several of which fit models that can also be fit using glm.

## Quick start

Model of $y$ as a function of $x$ when $y$ is a proportion glm y x, family(binomial)

Logit model of $y$ events occurring in 15 trials as a function of $x$
glm y x, family (binomial 15) link(logit)
Probit model of $y$ events as a function of $x$ using grouped data with group sizes $n$
glm y x, family (binomial n) link(probit)
Model of discrete $y$ with user-defined family myfamily and link mylink
glm y x, family (myfamily) link(mylink)
Bootstrap standard errors in a model of $y$ as a function of $x$ with a gamma family and log link glm y x, family (gamma) link(log) vce(bootstrap)

## Menu

Statistics $>$ Generalized linear models $>$ Generalized linear models (GLM)

## Syntax

glm depvar [indepvars] [if] [in] [weight] [, options]
options Description

## Model

family (familyname) distribution of depvar; default is family (gaussian)
link(linkname) link function; default is canonical link for family() specified
Model 2
noconstant
exposure (varname)
offset (varname)
constraints (constraints)
asis
mu(varname)
init (varname)
suppress constant term
include $\ln$ (varname) in model with coefficient constrained to 1 include varname in model with coefficient constrained to 1 apply specified linear constraints
retain perfect predictor variables
use varname as the initial estimate for the mean of depvar synonym for mu (varname)

SE/Robust
vce (vcetype)
vfactor(\#)
disp(\#)
scale(x2|dev|\#)
vcetype may be oim, robust, cluster clustvar, eim, opg,
bootstrap, jackknife, hac kernel, jackknife1, or unbiased
multiply variance matrix by scalar \#
quasilikelihood multiplier
set the scale parameter
Reporting
level(\#)
eform
nocnsreport
display_options
set confidence level; default is level (95)
report exponentiated coefficients
do not display constraints
control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

Maximization
ml
irls
maximize_options
fisher (\#)
search
noheader
notable
nodisplay
collinear
coeflegend
use maximum likelihood optimization; the default use iterated, reweighted least-squares optimization of the deviance control the maximization process; seldom used use the Fisher scoring Hessian or expected information matrix (EIM) search for good starting values
suppress header table from above coefficient table suppress coefficient table
suppress the output; iteration $\log$ is still displayed
keep collinear variables
display legend instead of statistics

## familyname

Description

## gaussian

igaussian
binomial $\left[\right.$ varname $_{N} \mid \#_{N}$ ]
poisson
nbinomial $\left[\#_{k} \mid \mathrm{ml}\right]$
gamma

Gaussian (normal) inverse Gaussian Bernoulli/binomial Poisson negative binomial gamma
linkname
identity
log
logit
probit
cloglog
power \#
opower \#
nbinomial
loglog
$\log \mathrm{c}$

## Description

## identity

$\log$
logit
probit
cloglog
power
odds power
negative binomial
$\log -\log$
log-complement
indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bayes, bootstrap, by, collect, fmm, fp, jackknife, mfp, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: glm and [FMM] fmm: glm.
vce(bootstrap), vce(jackknife), and vce(jackknife1) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
aweights are not allowed with the jackknife prefix; see $[R]$ jackknife.
vce(), vfactor(), disp(), scale(), irls, fisher(), noheader, notable, nodisplay, and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
noheader, notable, nodisplay, collinear, and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

$\qquad$ Model
family (familyname) specifies the distribution of depvar; family (gaussian) is the default. link (linkname) specifies the link function; the default is the canonical link for the family() specified (except for family (nbinomial)).

Model 2
noconstant, exposure(varname), offset(varname), constraints(constraints); see [R] Estimation options. constraints (constraints) is not allowed with irls.
asis forces retention of perfect predictor variables and their associated, perfectly predicted observations and may produce instabilities in maximization; see $[\mathrm{R}]$ probit. This option is allowed only with option family (binomial) with a denominator of 1.
mu(varname) specifies varname as the initial estimate for the mean of depvar. This option can be useful with models that experience convergence difficulties, such as family(binomial) models with power or odds-power links. init (varname) is a synonym.

## SE/Robust

vce (vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
In addition to the standard vcetypes, glm allows the following alternatives:
vce (eim) specifies that the EIM estimate of variance be used.
vce (jackknife1) specifies that the one-step jackknife estimate of variance be used.
vce (hac kernel [\#]) specifies that a heteroskedasticity- and autocorrelation-consistent (HAC) variance estimate be used. HAC refers to the general form for combining weighted matrices to form the variance estimate. There are three kernels built into glm. kernel is a user-written program or one of

```
nwest | gallant| anderson
```

\# specifies the number of lags. If \# is not specified, $N-2$ is assumed. If you wish to specify vce(hac...), you must tsset your data before calling glm.
vce (unbiased) specifies that the unbiased sandwich estimate of variance be used.
vfactor (\#) specifies a scalar by which to multiply the resulting variance matrix. This option allows you to match output with other packages, which may apply degrees of freedom or other small-sample corrections to estimates of variance.
disp(\#) multiplies the variance of depvar by \# and divides the deviance by \#. The resulting distributions are members of the quasilikelihood family. This option is allowed only with option irls.
scale( $\mathrm{x} 2|\mathrm{dev}| \#$ ) overrides the default scale parameter. This option is allowed only with Hessian (information matrix) variance estimates.
By default, scale(1) is assumed for the discrete distributions (binomial, Poisson, and negative binomial), and scale(x2) is assumed for the continuous distributions (Gaussian, gamma, and inverse Gaussian).
scale ( x 2 ) specifies that the scale parameter be set to the Pearson $\chi^{2}$ (or generalized $\chi^{2}$ ) statistic divided by the residual degrees of freedom, which is recommended by McCullagh and Nelder (1989) as a good general choice for continuous distributions.
scale (dev) sets the scale parameter to the deviance divided by the residual degrees of freedom. This option provides an alternative to scale (x2) for continuous distributions and overdispersed or underdispersed discrete distributions. This option is allowed only with option irls.
scale(\#) sets the scale parameter to \#. For example, using scale(1) in family (gamma) models results in exponential-errors regression. Additional use of link(log) rather than the default link (power -1) for family (gamma) essentially reproduces Stata's streg, dist (exp) nohr command (see [ST] streg) if all the observations are uncensored.
level (\#); see [R] Estimation options.
eform displays the exponentiated coefficients and corresponding standard errors and confidence intervals. For family(binomial) link(logit) (that is, logistic regression), exponentiation results are odds ratios; for family (nbinomial) link(log) (that is, negative binomial regression) and for family (poisson) link(log) (that is, Poisson regression), exponentiated coefficients are incidence-rate ratios.
nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\% fmt), sformat (\% $\% m t$ ), and nolstretch; see [R] Estimation options.
$\qquad$ Maximization
ml requests that optimization be carried out using Stata's ml commands and is the default.
irls requests iterated, reweighted least-squares (IRLS) optimization of the deviance instead of NewtonRaphson optimization of the log likelihood. If the irls option is not specified, the optimization is carried out using Stata's ml commands, in which case all options of ml maximize are also available.
maximize_options: difficult, technique (algorithm_spec), iterate (\#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(\#), ltolerance(\#), nrtolerance(\#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization method to technique (bhhh) resets the default vcetype to vce (opg).
If option irls is specified, only maximize_options iterate(), nolog, trace, and ltolerance() are allowed. With irls specified, the convergence criterion is satisfied when the absolute change in deviance from one iteration to the next is less than or equal to ltolerance(), where ltolerance ( $1 \mathrm{e}-6$ ) is the default.
fisher (\#) specifies the number of Newton-Raphson steps that should use the Fisher scoring Hessian or EIM before switching to the observed information matrix (OIM). This option is useful only for Newton-Raphson optimization (and not when using irls).
search specifies that the command search for good starting values. This option is useful only for Newton-Raphson optimization (and not when using irls).

The following options are available with glm but are not shown in the dialog box: noheader suppresses the header information from the output. The coefficient table is still displayed. notable suppresses the table of coefficients from the output. The header information is still displayed. nodisplay suppresses the output. The iteration $\log$ is still displayed.
collinear, coeflegend; see [R] Estimation options. collinear is not allowed with irls.

## Remarks and examples

Remarks are presented under the following headings:

## General use

Variance estimators
User-defined functions

## General use

glm fits generalized linear models of $y$ with covariates $\mathbf{x}$ :

$$
g\{E(y)\}=\mathbf{x} \boldsymbol{\beta}, \quad y \sim F
$$

$g()$ is called the link function, and $F$ is the distributional family. Substituting various definitions for $g()$ and $F$ results in a surprising array of models. For instance, if $y$ is distributed as Gaussian (normal) and $g()$ is the identity function, we have

$$
E(y)=\mathbf{x} \boldsymbol{\beta}, \quad y \sim \text { Normal }
$$

or linear regression. If $g()$ is the logit function and $y$ is distributed as Bernoulli, we have

$$
\operatorname{logit}\{E(y)\}=\mathbf{x} \boldsymbol{\beta}, \quad y \sim \text { Bernoulli }
$$

or logistic regression. If $g()$ is the natural $\log$ function and $y$ is distributed as Poisson, we have

$$
\ln \{E(y)\}=\mathbf{x} \boldsymbol{\beta}, \quad y \sim \text { Poisson }
$$

or Poisson regression, also known as the log-linear model. Other combinations are possible.
Although glm can be used to perform linear regression (and, in fact, does so by default), this regression should be viewed as an instructional feature; regress produces such estimates more quickly, and many postestimation commands are available to explore the adequacy of the fit; see [ $R$ ] regress and [ $R$ ] regress postestimation.

In any case, you specify the link function by using the link() option and specify the distributional family by using family(). The available link functions are

| Link function | glm option |
| :--- | :--- |
| identity | link(identity) |
| log | link(log) |
| logit | link(logit) |
| probit | link(probit) |
| complementary log-log | link(cloglog) |
| odds power | link(opower \#) |
| power | link(power \#) |
| negative binomial | link(nbinomial) |
| log-log | link(loglog) |
| log-complement | link(logc) |

Define $\mu=E(y)$ and $\eta=g(\mu)$, meaning that $g(\cdot)$ maps $E(y)$ to $\eta=\mathbf{x} \boldsymbol{\beta}+$ offset.

Link functions are defined as follows:
identity is defined as $\eta=g(\mu)=\mu$.
$\log$ is defined as $\eta=\ln (\mu)$.
logit is defined as $\eta=\ln \{\mu /(1-\mu)\}$, the natural $\log$ of the odds.
probit is defined as $\eta=\Phi^{-1}(\mu)$, where $\Phi^{-1}()$ is the inverse Gaussian cumulative.
cloglog is defined as $\eta=\ln \{-\ln (1-\mu)\}$.
opower is defined as $\eta=\left[\{\mu /(1-\mu)\}^{n}-1\right] / n$, the power of the odds. The function is generalized so that link (opower 0 ) is equivalent to link(logit), the natural log of the odds. power is defined as $\eta=\mu^{n}$. Specifying link(power 1) is equivalent to specifying link(identity). The power function is generalized so that $\mu^{0} \equiv \ln (\mu)$. Thus, link(power 0 ) is equivalent to $\operatorname{link}(\log )$. Negative powers are, of course, allowed.
nbinomial is defined as $\eta=\ln \{\mu /(\mu+k)\}$, where $k=1$ if family (nbinomial) is specified, $k=\#_{k}$ if family (nbinomial $\#_{k}$ ) is specified, and $k$ is estimated via maximum likelihood if family (nbinomial ml) is specified.
$\log l o g$ is defined as $\eta=-\ln \{-\ln (\mu)\}$.
loge is defined as $\eta=\ln (1-\mu)$.
The available distributional families are

| Family | glm option |
| :--- | :--- |
| Gaussian (normal) | family (gaussian) |
| inverse Gaussian | family (igaussian) |
| Bernoulli/binomial | family (binomial) |
| Poisson | family (poisson) |
| negative binomial | family (nbinomial) |
| gamma | family (gamma) |

family(normal) is a synonym for family (gaussian).
The binomial distribution can be specified as 1) family (binomial), 2) family (binomial $\#_{N}$ ), or 3) family (binomial varname ${ }_{N}$ ). In case $2, \#_{N}$ is the value of the binomial denominator $N$, the number of trials. Specifying family (binomial 1) is the same as specifying family (binomial). In case 3, varname $N_{N}$ is the variable containing the binomial denominator, allowing the number of trials to vary across observations.

The negative binomial distribution can be specified as 1) family(nbinomial), 2) family (nbinomial $\#_{k}$ ), or 3) family (nbinomial ml ). Omitting $\#_{k}$ is equivalent to specifying family (nbinomial 1). In case 3, the value of $\#_{k}$ is estimated via maximum likelihood. The value $\#_{k}$ enters the variance and deviance functions. Typical values range between 0.01 and 2 ; see the technical note below.

You do not have to specify both family() and link(); the default link() is the canonical link for the specified family() (except for nbinomial):

| Family | Default link |
| :--- | :--- |
| family (gaussian) | link(identity) |
| family (igaussian) | link(power -2) |
| family (binomial) | link(logit) |
| family (poisson) | link(log) |
| family (nbinomial) | link(log) |
| family (gamma) | link(power -1) |

If you specify both family() and link(), not all combinations make sense. You may choose from the following combinations:

|  | identity | $\log$ | logit | probit | cloglog | power | opower | nbinomial | $\operatorname{loglog}$ | $\operatorname{logc}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Gaussian | x | x |  |  |  | x |  |  |  |  |
| inverse Gaussian | x | x |  |  |  | x |  |  |  |  |
| binomial | x | x | x | x | x | x | x |  | x | x |
| Poisson | x | x |  |  |  | x |  |  |  |  |
| negative binomial | x | x |  |  |  | x |  | x |  |  |
| gamma | x | x |  |  | x |  |  |  |  |  |

## Technical note

Some family() and link() combinations result in models already fit by Stata. These are

| family () | link() | Options | Equivalent Stata command |
| :---: | :---: | :---: | :---: |
| gaussian | identity | nothing $\mid$ irls ${ }^{\text {irls }}$ vce (oim) | regress |
| gaussian | identity | ```t(var) vce(hac nwest #) vfactor(#v)``` | newey, t (var) lag(\#) (see note 1) |
| binomial | cloglog | nothing \|irls vce(oim) | cloglog (see note 2) |
| binomial | probit | nothing \|irls vce(oim) | probit (see note 2) |
| binomial | logit | nothing $\mid$ irls $\mid$ irls vce(oim) | logit or logistic (see note 3) |
| poisson | log | nothing\|irls|irls vce(oim) | poisson (see note 3) |
| nbinomial | log | nothing\|irls vce(oim) | nbreg (see note 4) |
| gamma | log | scale(1) | streg, dist (exp) nohr (see note 5) |

## Notes:

1. The variance factor $\#_{v}$ should be set to $n /(n-k)$, where $n$ is the number of observations and $k$ the number of regressors. If the number of regressors is not specified, the estimated standard errors will, as a result, differ by this factor.
2. Because the link is not the canonical link for the binomial family, you must specify the vee (oim) option if using irls to get equivalent standard errors. If irls is used without vce(oim), the regression coefficients will be the same but the standard errors will be only asymptotically equivalent. If no options are specified (nothing), glm will optimize using Newton-Raphson, making it equivalent to the other Stata command.

See $[R]$ cloglog and $[R]$ probit for more details about these commands.
3. Because the canonical link is being used, the standard errors will be equivalent whether the EIM or the OIM estimator of variance is used.
4. Family negative binomial, log-link models-also known as negative binomial regression models - are used for data with an overdispersed Poisson distribution. Although glm can be used to fit such models, using Stata's maximum likelihood nbreg command is probably better. In the GLM approach, you specify family (nbinomial $\#_{k}$ ) and then search for a $\#_{k}$ that results in the deviance-based dispersion being 1 . You can also specify family (nbinomial ml) to estimate $\#_{k}$ via maximum likelihood, which will report the same value returned from nbreg. However, nbreg also reports a confidence interval for it; see [R] nbreg and Rogers (1993). Of course, glm allows links other than log, and for those links, including the canonical nbinomial link, you will need to use glm.
5. glm can be used to estimate parameters from exponential regressions, but this method requires specifying scale(1). However, censoring is not available. Censored exponential regression may be modeled using glm with family (poisson). The $\log$ of the original response is entered into a Poisson model as an offset, whereas the new response is the censor variable. The result of such modeling is identical to the log relative hazard parameterization of streg, dist(exp) nohr. See [ST] streg for details about the streg command.
In general, where there is overlap between a capability of glm and that of some other Stata command, we recommend using the other Stata command. Our recommendation is not because of some inferiority of the GLM approach. Rather, those other commands, by being specialized, provide options and ancillary commands that are missing in the broader glm framework. Nevertheless, glm does produce the same answers where it should.
Special note. When equivalence is expected, for some datasets, you may still see very slight differences in the results, most often only in the later digits of the standard errors. When you compare glm output to an equivalent Stata command, these tiny discrepancies arise for many reasons:
a. glm uses a general methodology for starting values, whereas the equivalent Stata command may be more specialized in its treatment of starting values.
b. When using a canonical link, glm, irls should be equivalent to the maximum likelihood method of the equivalent Stata command, yet the convergence criterion is different (one is for deviance, the other for log likelihood). These discrepancies are easily resolved by adjusting one convergence criterion to correspond to the other.
c. When both glm and the equivalent Stata command use Newton-Raphson, small differences may still occur if the Stata command has a different default convergence criterion from that of glm. Adjusting the convergence criterion will resolve the difference. See [R] ml and [R] Maximize for more details.

## $>$ Example 1

In example 1 of $[\mathrm{R}]$ logistic, we fit a model based on data from a study of risk factors associated with low birthweight (Hosmer, Lemeshow, and Sturdivant 2013, 24). We can replicate the estimation by using glm:
. use https://www.stata-press.com/data/r18/lbw
(Hosmer \& Lemeshow data)
. glm low age lwt i.race smoke ptl ht ui, family (binomial) link(logit)
Iteration 0: Log likelihood $=-101.0213$
Iteration 1: Log likelihood $=-100.72519$
Iteration 2: Log likelihood $=$-100.724
Iteration 3: Log likelihood $=-100.724$
Generalized linear models Number of obs $=\quad 189$

| Optimization $: ~ M L ~$ | Residual df | $=$ | 180 |
| :--- | :--- | :--- | :--- |

Deviance $=201.4479911 \quad(1 / \mathrm{df})$ Deviance $=1.119156$

Pearson $=182.0233425 \quad(1 / d f)$ Pearson $=1.011241$
Variance function: $V(u)=u *(1-u)$
[Bernoulli]
Link function : $g(u)=\ln (u /(1-u))$
[Logit]
AIC $=1.1611$
Log likelihood $=-100.7239956 \quad$ BIC $=-742.0665$

|  | OIM |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| low | Coefficient | std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| age | -.0271003 | .0364504 | -0.74 | 0.457 | -.0985418 | .0443412 |
| lwt | -.0151508 | .0069259 | -2.19 | 0.029 | -.0287253 | -.0015763 |
| race |  |  |  |  |  |  |
| Black | 1.262647 | .5264101 | 2.40 | 0.016 | .2309024 | 2.294392 |
| Other | .8620792 | .4391532 | 1.96 | 0.050 | .0013548 | 1.722804 |
| smoke | .9233448 | .4008266 | 2.30 | 0.021 | .137739 | 1.708951 |
| ptl | .5418366 | .346249 | 1.56 | 0.118 | -.136799 | 1.220472 |
| ht | 1.832518 | .6916292 | 2.65 | 0.008 | .4769494 | 3.188086 |
| ui | .7585135 | .4593768 | 1.65 | 0.099 | -.1418484 | 1.658875 |
| _cons | .4612239 | 1.20459 | 0.38 | 0.702 | -1.899729 | 2.822176 |

glm, by default, presents coefficient estimates, whereas logistic presents the exponentiated coefficients - the odds ratios. glm's eform option reports exponentiated coefficients, and glm, like Stata's other estimation commands, replays results.

| Generalized linear models | Number of obs |  | 189 |

| ptl | 1.719161 | .5952579 | 1.56 | 0.118 | .8721455 | 3.388787 |
| ht | 6.249602 | 4.322408 | 2.65 | 0.008 | 1.611152 | 24.24199 |
| ui | 2.1351 | .9808153 | 1.65 | 0.099 | .8677528 | 5.2534 |
| _cons | 1.586014 | 1.910496 | 0.38 | 0.702 | .1496092 | 16.8134 |

Note: _cons estimates baseline odds.
These results are the same as those reported in example 1 of $[R]$ logistic.
Included in the output header are values for the Akaike (1973) information criterion (AIC) and the Bayesian information criterion (BIC) (Raftery 1995). Both are measures of model fit adjusted for the number of parameters that can be compared across models. In both cases, a smaller value generally indicates a better model fit. AIC is based on the log likelihood and thus is available only when Newton-Raphson optimization is used. BIC is based on the deviance and thus is always available.

## Technical note

The values for AIC and BIC reported in the output after glm are different from those reported by estat ic:

- estat ic

Akaike's information criterion and Bayesian information criterion

| Model | N | ll(null) | ll (model) | df | AIC | BIC |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| . | 189 |  | . | -100.724 | 9 | 219.448 |

Note: BIC uses $N=$ number of observations. See [R] IC note.
There are various definitions of these information criteria (IC) in the literature; glm and estat ic use different definitions. glm bases its computation of the BIC on deviance, whereas estat ic uses the likelihood. Both glm and estat ic use the likelihood to compute the AIC; however, the AIC from estat ic is equal to $N$, the number of observations, times the AIC from glm. Refer to Methods and formulas in this entry and $[\mathrm{R}]$ estat ic for the references and formulas used by glm and estat ic, respectively, to compute AIC and BIC. Inferences based on comparison of IC values reported by glm
for different GLM models will be equivalent to those based on comparison of IC values reported by estat ic after glm.

## > Example 2

We use data from an early insecticide experiment, given in Pregibon (1980). The variables are ldose, the log dose of insecticide; $n$, the number of flour beetles subjected to each dose; and $r$, the number killed.

```
. use https://www.stata-press.com/data/r18/ldose
. list, sep(4)
```

| ldose | n | r |
| :---: | ---: | ---: |
| 1.6907 | 59 | 6 |
| 1.7242 | 60 | 13 |
| 1.7552 | 62 | 18 |
| 1.7842 | 56 | 28 |
| 1.8113 | 63 | 52 |
| 1.8369 | 59 | 53 |
| 1.861 | 62 | 61 |
| 1.8839 | 60 | 60 |

The aim of the analysis is to estimate a dose-response relationship between $p$, the proportion killed, and $X$, the $\log$ dose.

As a first attempt, we will formulate the model as a linear logistic regression of $p$ on ldose; that is, we will take the logit of $p$ and represent the dose-response curve as a straight line in $X$ :

$$
\ln \{p /(1-p)\}=\beta_{0}+\beta_{1} X
$$

Because the data are grouped, we cannot use Stata's logistic command to fit the model. Instead, we will fit the model by using glm:

| Iteration 0: Log likelihood $=-18.824848$ |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration 1: Log likelihood $=-18.715271$ |  |  |  |  |  |  |
| Iteration 2: Log likelihood $=-18.715123$ |  |  |  |  |  |  |
| Iteration 3: Log likelihood $=-18.715123$ |  |  |  |  |  |  |
| Generalized linear models |  |  |  | Numb | of obs | 8 |
| Optimization : ML |  |  |  | Resi | al df | 6 |
|  |  |  |  | Sca | parameter | 1 |
| Deviance $=11.23220702$ |  |  |  | (1/d | Deviance | 1.872035 |
| Pearson $=10.0267936$ |  |  |  | (1/d | Pearson | 1.671132 |
| Variance function: $V(\mathrm{u})=\mathrm{u} *(1-\mathrm{u} / \mathrm{n})$ |  |  |  | [Binomial] |  |  |
| Link function : $\mathrm{g}(\mathrm{u})=\ln (\mathrm{u} /(\mathrm{n}-\mathrm{u})$ ) |  |  |  | [Logit] |  |  |
|  |  |  |  | AIC |  | 5.178781 |
| Log likelihood = -18.71512262 |  |  |  | BIC |  | -1.244442 |
| r | Coefficient | $\begin{gathered} \text { OIM } \\ \text { std. err. } \end{gathered}$ | z | $P>\|z\|$ | [95\% conf | interval] |
| ldose | 34.27034 | 2.912141 | 11.77 | 0.000 | 28.56265 | 39.97803 |
| _cons | -60.71747 | 5.180713 | -11.72 | 0.000 | -70.87149 | -50.56346 |

We specified family (binomial $n$ ), meaning that variable $n$ contains the denominator.
An alternative model, which gives asymmetric sigmoid curves for $p$, involves the complementary $\log -\log$, or cloglog, function:

$$
\ln \{-\ln (1-p)\}=\beta_{0}+\beta_{1} X
$$

We fit this model by using glm:

```
. glm r ldose, family(binomial n) link(cloglog)
Iteration 0: Log likelihood = -14.883594
Iteration 1: Log likelihood = -14.822264
Iteration 2: Log likelihood = -14.822228
Iteration 3: Log likelihood = -14.822228
Generalized linear models Number of obs = 8
Optimization : ML
Deviance = 3.446418004
Pearson = 3.294675153
Variance function: V(u) = u*(1-u/n)
Link function : g(u) = ln}(-\operatorname{ln}(1-u/n)
Log likelihood = -14.82222811 BIC = -9.030231
```

|  | OIM |  |  |  |  |  |
| ---: | ---: | :---: | ---: | ---: | ---: | ---: |
| r | Coefficient | std. err. | z | P>\|z| | [95\% conf. interval] |  |
| ldose | 22.04118 | 1.793089 | 12.29 | 0.000 | 18.52679 | 25.55557 |
| _cons | -39.57232 | 3.229047 | -12.26 | 0.000 | -45.90114 | -33.24351 |

The cloglog model is preferred; the deviance for the logistic model, 11.23, is much higher than the deviance for the cloglog model, 3.45. This change also is evident by comparing log likelihoods, or equivalently, AIC values.

This example also shows the advantage of the glm command-we can vary assumptions easily. Note the minor difference in what we typed to obtain the logistic and cloglog models:

```
. glm r ldose, family(binomial n) link(logit)
. glm r ldose, family(binomial n) link(cloglog)
```

If we were performing this work for ourselves, we would have typed the commands in a more abbreviated form:

```
. glm r ldose, f(b n) l(l)
. glm r ldose, f(b n) l(cl)
```

## - Technical note

Factor variables may be used with glm. Say that, in the example above, we had ldose, the $\log$ dose of insecticide; $n$, the number of flour beetles subjected to each dose; and $r$, the number killed-all as before-except that now we have results for three different kinds of beetles. Our hypothetical data include beetle, which contains the values 1 ("Destructive flour"), 2 ("Red flour"), and 3 ("Mealworm").
. use https://www.stata-press.com/data/r18/beetle
. list, sep(0)

| beetle | ldose | n | r |
| :--- | ---: | ---: | ---: |
| Destructive flour | 1.6907 | 59 | 6 |
| Destructive flour | 1.7242 | 60 | 13 |
| Destructive flour | 1.7552 | 62 | 18 |
| Destructive flour | 1.7842 | 56 | 28 |
| Destructive flour | 1.8113 | 63 | 52 |
| (output omitted ) |  |  |  |
| Mealworm | 1.861 | 64 | 23 |
| Mealworm | 1.8839 | 58 | 22 |

Let's assume that, at first, we wish merely to add a shift factor for the type of beetle. We could type

| Iteration 0: Log likelihood = -79.012269 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Iteration 1: Log likelihood $=-76.94951$ |  |  |  |  |  |  |
| Iteration 2: Log likelihood $=-76.945645$ |  |  |  |  |  |  |
| Iteration 3: Log likelihood = -76.945645 |  |  |  |  |  |  |
| Generalized linear models |  |  |  | Numb | of obs | 24 |
| Optimization : ML |  |  |  | Resi | al df | 20 |
|  |  |  |  | Scal | parameter | 1 |
| Deviance $\quad=73.76505595$ |  |  |  | (1/d | Deviance | 3.688253 |
| Pearson $=71.8901173$ |  |  |  | (1/d | Pearson | 3.594506 |
| Variance function: $V(u)=u *(1-u / n)$ |  |  |  | [Binomial] |  |  |

We find strong evidence that the insecticide works differently on the mealworm. We now check whether the curve is merely shifted or also differently sloped:

| Iteration 0: Log likelihood $=-67.270188$ |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| ldose | 22.04118 | 1.793089 | 12.29 | 0.000 | 18.52679 | 25.55557 |
| beetle\#c.ldose |  |  |  |  |  |  |
| Red flour | . 3838708 | 2.478477 | 0.15 | 0.877 | -4.473855 | 5.241596 |
| Mealworm | -10.726 | 2.526412 | -4.25 | 0.000 | -15.67768 | -5.774321 |
| _cons | -39.57232 | 3.229047 | -12.26 | 0.000 | -45.90114 | -33.24351 |

We find that the (complementary $\log -\log$ ) dose-response curve for the mealworm has roughly half the slope of that for the destructive flour beetle.

See [U] 26 Working with categorical data and factor variables; what is said there concerning linear regression is applicable to any GLM model.

## Variance estimators

glm offers many variance options and gives different types of standard errors when used in various combinations. We highlight some of them here, but for a full explanation, see Hardin and Hilbe (2018).

## > Example 3

Continuing with our flour beetle data, we rerun the most recently displayed model, this time requesting estimation via IRLS.

```
. use https://www.stata-press.com/data/r18/beetle
. glm r beetle##c.ldose, f(bin n) l(cloglog) ltol(1e-13) irls
Iteration 1: Deviance = 54.41414
Iteration 2: Deviance = 50.19424
Iteration 3: Deviance = 50.16973
    (output omitted)
\begin{tabular}{llll} 
Generalized linear models & Number of obs & \(=\) & 24 \\
Optimization & : MQL Fisher scoring & (IRLS EIM) & Residual df \\
& \(=50.16972096\) & Scale parameter \(=\) & 18 \\
Deviance & \(=49.28422528\) & \((1 / d f)\) Deviance & \(=\) \\

& & BIC & \(=-7.035248\)
\end{tabular}
```

| $r$ | Coefficient | std. err. | $z$ | P>\|z| | [95\% conf. interval] |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| beetle <br> Red flour <br> Mealworm | -.79933 | 4.586649 | -0.17 | 0.862 | -9.788997 | 8.190337 |
| ldose | 22.04118 | 1.79741 | 4.624834 | 3.85 | 0.000 | 8.7229 | 26.85192

Note our use of the ltol() option, which, although unrelated to our discussion on variance estimation, was used so that the regression coefficients would match those of the previous Newton-Raphson (NR) fit.

Because IRLS uses the EIM for optimization, the variance estimate is also based on EIM. If we want optimization via IRLS but the variance estimate based on OIM, we specify glm, irls vce (oim):
glm r beetle\#\#c.ldose, f(b) l ( cl ) ltol(1e-15) irls vce(oim) noheader nolog

| r | Coefficient | $\begin{gathered} \text { OIM } \\ \text { std. err. } \end{gathered}$ | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| beetle |  |  |  |  |  |  |
| Red flour | -. 79933 | 4.470882 | -0.18 | 0.858 | -9.562098 | 7.963438 |
| Mealworm | 17.78741 | 4.586429 | 3.88 | 0.000 | 8.798172 | 26.77664 |
| ldose | 22.04118 | 1.793089 | 12.29 | 0.000 | 18.52679 | 25.55557 |
| beetle\#c.ldose |  |  |  |  |  |  |
| Red flour | . 3838708 | 2.478477 | 0.15 | 0.877 | -4.473855 | 5.241596 |
| Mealworm | -10.726 | 2.526412 | -4.25 | 0.000 | -15.67768 | -5.774321 |
| _cons | -39.57232 | 3.229047 | -12.26 | 0.000 | -45.90114 | -33.24351 |

This approach is identical to NR except for the convergence path. Because the cloglog link is not the canonical link for the binomial family, EIM and OIM produce different results. Both estimators, however, are asymptotically equivalent.

Going back to NR, we can also specify vce(robust) to get the Huber/White/sandwich estimator of variance:

| r | Coefficient | Robust std. err. | z | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| beetle |  |  |  |  |  |  |
| Red flour | -. 79933 | 5.733049 | -0.14 | 0.889 | -12.0359 | 10.43724 |
| Mealworm | 17.78741 | 5.158477 | 3.45 | 0.001 | 7.676977 | 27.89784 |
| ldose | 22.04118 | . 8998551 | 24.49 | 0.000 | 20.27749 | 23.80486 |
| beetle\#c.ldose |  |  |  |  |  |  |
| Red flour | . 3838708 | 3.174427 | 0.12 | 0.904 | -5.837892 | 6.605633 |
| Mealworm | -10.726 | 2.800606 | -3.83 | 0.000 | -16.21508 | -5. 236912 |
| _cons | -39.57232 | 1.621306 | -24.41 | 0.000 | -42.75003 | -36.39462 |

The sandwich estimator gets its name from the form of the calculation-it is the multiplication of three matrices, with the outer two matrices (the "bread") set to the OIM variance matrix. When irls is used along with vce (robust), the EIM variance matrix is instead used as the bread. Using a result from McCullagh and Nelder (1989), Newson (1999) points out that the EIM and OIM variance matrices are equivalent under the canonical link. Thus if irls is specified with the canonical link, the resulting variance is labeled "Robust". When the noncanonical link for the family is used, which is the case in the example below, the EIM and OIM variance matrices differ, so the resulting variance is labeled "Semirobust".

```
. glm r beetle##c.ldose, f(b n) l(cl) irls ltol(1e-15) vce(robust) noheader
> nolog
```

| r | Coefficient | Semirobust std. err. | z | $P>\|z\|$ | [95\% conf. interval] |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| beetle |  |  |  |  |  |  |
| Red flour | -. 79933 | 6.288963 | -0.13 | 0.899 | -13.12547 | 11.52681 |
| Mealworm | 17.78741 | 5.255307 | 3.38 | 0.001 | 7.487194 | 28.08762 |
| ldose | 22.04118 | . 9061566 | 24.32 | 0.000 | 20.26514 | 23.81721 |

| Mealworm | -10.726 | 2.855897 | -3.76 | 0.000 | -16.32345 | -5.128542 |
| _cons | -39.57232 | 1.632544 | -24.24 | 0.000 | -42.77205 | -36.3726 |

The outer product of the gradient ( OPG ) estimate of variance is one that avoids the calculation of second derivatives. It is equivalent to the "middle" part of the sandwich estimate of variance and can be specified by using glm, vce (opg), regardless of whether NR or IRLS optimization is used.

| r | Coefficient | $\begin{gathered} \text { OPG } \\ \text { std. err. } \end{gathered}$ | z | $P>\|z\|$ | [95\% conf. | interval] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| beetle |  |  |  |  |  |  |
| Red flour | -. 79933 | 6.664045 | -0.12 | 0.905 | -13.86062 | 12.26196 |
| Mealworm | 17.78741 | 6.838505 | 2.60 | 0.009 | 4.384183 | 31.19063 |
| ldose | 22.04118 | 3.572983 | 6.17 | 0.000 | 15.03826 | 29.0441 |
| beetle\#c.ldose |  |  |  |  |  |  |
| Red flour | . 3838708 | 3.700192 | 0.10 | 0.917 | -6.868372 | 7.636114 |
| Mealworm | -10.726 | 3.796448 | -2.83 | 0.005 | -18.1669 | -3.285097 |
| _cons | -39.57232 | 6.433101 | -6.15 | 0.000 | -52.18097 | -26.96368 |

The OPG estimate of variance is a component of the BHHH (Berndt et al. 1974) optimization technique. This method of optimization is also available with glm with the technique() option; however, the technique() option is not allowed with the irls option.

## > Example 4

The Newey-West (1987) estimator of variance is a sandwich estimator with the "middle" of the sandwich modified to account for possible autocorrelation between the observations. These estimators are a generalization of those given by the Stata command newey for linear regression. See [TS] newey for more details.

For example, consider the dataset given in [TS] newey, which has time-series measurements on usr and idle. We want to perform a linear regression with Newey-West standard errors.
. use https://www.stata-press.com/data/r18/idle2
. list usr idle time

| usr | idle | time |
| :---: | :---: | :---: |
| 0 | 100 | 1 |
| 0 | 100 | 2 |
| 0 | 97 | 3 |
| 1 | 98 | 4 |
| 2 | 94 | 5 |$|$| (output omitted) |  |  |
| :---: | :---: | :---: |
| 1 | 98 | 29 |
| 1 | 98 | 30 |

Examining Methods and formulas of [TS] newey, we see that the variance estimate is multiplied by a correction factor of $n /(n-k)$, where $k$ is the number of regressors. glm, vce (hac ...) does not make this correction, so to get the same standard errors, we must use the vfactor() option within glm to make the correction manually.

| display 30/28 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $1.0714286$ <br> . tsset time |  |  |  |  |  |  |
|  |  |  |  |  |  |  |
| ```Time variable: time, 1 to 30 Delta: 1 unit``` |  |  |  |  |  |  |
| . glm usr idle, vce(hac nwest 3) vfactor(1.0714286) |  |  |  |  |  |  |
| Iteration 0: Log likelihood = -71.743396 |  |  |  |  |  |  |
| Generalized linear models |  |  |  | Num | of obs | 30 |
| Optimization | : ML |  |  | Res | al df | 28 |
|  |  |  |  | Scal | parameter | 7.493297 |
| Deviance $\quad=209.8123165$ |  |  |  | (1/d | Deviance | 7.493297 |
| Pearson $\quad=209.8123165$ |  |  |  | (1/d | Pearson | 7.493297 |
| Variance function: V u$)=1$ |  |  |  | [Gau | ian] |  |
| Link function : $\mathrm{g}(\mathrm{u})=\mathrm{u}$ |  |  |  | [Id | ity] |  |
| HAC kernel (lags) : Newey-West (3) |  |  |  |  |  |  |
|  |  |  |  | AIC |  | 4.916226 |
| Log likelihood | $=-71.74339627$ |  |  | BIC |  | 114.5788 |
| usr | Coefficient | $\begin{gathered} \text { HAC } \\ \text { std. err. } \end{gathered}$ | z | $P>\|z\|$ | [95\% con | interval] |
| idle | -. 2281501 | . 0690928 | -3.30 | 0.001 | -. 3635694 | -. 0927307 |
| _cons | 23.13483 | 6.327033 | 3.66 | 0.000 | 10.73407 | 35.53558 |

The glm command above reproduces the results given in [TS] newey. We may now generalize this output to models other than simple linear regression and to different kernel weights.

glm also offers variance estimators based on the bootstrap (resampling your data with replacement) and the jackknife (refitting the model with each observation left out in succession). Also included is the one-step jackknife estimate, which, instead of performing full reestimation when each observation is omitted, calculates a one-step NR estimate, with the full data regression coefficients as starting values.

See Hardin and Hilbe (2018) for a full discussion of the variance options that go with glm and, in particular, of how the different variance estimators are modified when vce (cluster clustvar) is specified. Finally, not all variance options are supported with all types of weights. See help glm for a current table of the variance options that are supported with the different weights.

## User-defined functions

glm may be called with a community-contributed link function, variance (family) function, NeweyWest kernel-weight function, or any combination of the three.

## Syntax of link functions

```
program progname
    version 18.0 // (or version 18.5 for StataNow)
    args todo eta mu return
    if 'todo' == -1 {
            /* Set global macros for output */
            global SGLM_lt "title for link function"
            global SGLM_lf "subtitle showing link definition"
            exit
    }
    if 'todo' == 0 {
            /* set }\eta=g(\mu) *
            /* Intermediate calculations go here */
            generate double 'eta' = ...
            exit
    }
    if 'todo' == 1 {
            /* set }\mu=\mp@subsup{g}{}{-1}(\eta)*
            /* Intermediate calculations go here */
            generate double 'mu' = ...
            exit
    }
    if 'todo' == 2 {

    /* Intermediate calculations go here */
    generate double 'return' = ...
    exit
}
display as error "Unknown call to glm variance function"
exit 198
end
```

## Syntax of Newey-West kernel-weight functions

```
program progname, rclass
    version 18.0 // (or version 18.5 for StataNow)
    args G j
    /* G is the maximum lag */
    /* j is the current lag */
    /* Intermediate calculations go here */
    return scalar wt = computed weight
    return local setype "Newey-West"
    return local sewtype "name of kernel"
end
```

## Global macros available for community-contributed programs

| Global macro | Description |
| :--- | :--- |
| SGLM_V | program name of variance (family) evaluator |
| SGLM_L | program name of link evaluator |
| dependent variable name |  |
| SGLM_y | binomial denominator |
| SGLM_m | negative binomial $k$ |
| SGLM_a | power if power() or opower() is used, or |
| SGLM_p | an argument from a user-specified link function |
|  | indicator; set to one if scale is equal to one |
| SGLM_s1 | value of scale parameter |

## > Example 5

Suppose that we wish to perform Poisson regression with a log-link function. Although this regression is already possible with standard glm, we will write our own version for illustrative purposes.

Because we want a $\log \operatorname{lin} k, \eta=g(\mu)=\ln (\mu)$, and for a Poisson family the variance function is $V(\mu)=\mu$.

The Poisson density is given by

$$
f\left(y_{i}\right)=\frac{e^{-\exp \left(\mu_{i}\right)} e^{\mu_{i} y_{i}}}{y_{i}!}
$$

resulting in a log likelihood of

$$
L=\sum_{i=1}^{n}\left\{-e^{\mu_{i}}+\mu_{i} y_{i}-\ln \left(y_{i}!\right)\right\}
$$

The squared deviance of the $i$ th observation for the Poisson family is given by

$$
d_{i}^{2}= \begin{cases}2 \widehat{\mu}_{i} & \text { if } y_{i}=0 \\ 2\left\{y_{i} \ln \left(y_{i} / \widehat{\mu}_{i}\right)-\left(y_{i}-\widehat{\mu}_{i}\right)\right\} & \text { otherwise }\end{cases}
$$

We now have enough information to write our own Poisson-log glm module. We create the file mylog.ado, which contains

```
program mylog
    version 18.0 // (or version 18.5 for StataNow)
    args todo eta mu return
    if 'todo' == -1 \{
            global SGLM_lt "My Log" // Titles for output
                global SGLM_lf "ln(u)"
                exit
    \}
    if 'todo' == 0 \{
        gen double 'eta' \(=\ln (' m u ') \quad / / \quad \eta=\ln (\mu)\)
        exit
    \}
    if 'todo' == 1 \{

    gen double 'return' = 1/(6*sqrt('mu'))
    exit
}
di as error "Unknown call to glm variance function"
error }19
```

end

Notes:

1. glim_mu is a Stata program that will, at each iteration, bring $\widehat{\mu}$ back into its plausible range, should it stray out of it. Here glim_mu is called with the arguments zero and missing, meaning that zero is the lower bound of $\widehat{\mu}$ and there exists no upper bound-such is the case for Poisson models.
2. Here the initial value of $\eta$ is easy because we intend to fit this model with our user-defined log link. In general, however, the initialization may need to vary according to the link to obtain convergence. If so, the global macro SGLM_L is used to determine which link is being utilized.
3. The Anscombe formula is given here because we know it. If we were not interested in Anscombe residuals, we could merely set 'return' to missing. Also, the local macro y is set either to SGLM_y if it is in current estimation or to e (depvar) if this function is being accessed by predict.
4. If we were not interested in ML estimation, we could omit this code entirely and just leave an exit statement in its place. Similarly, if we were not interested in deviance or IRLS optimization, we could set 'return' in the deviance portion of the code ('todo'==3) to missing.
5. This code defines the term to be added to the predicted residuals if the adjusted option is specified. Again, if we were not interested, we could set 'return' to missing.
We can now test our Poisson-log module by running it on the airline data presented in $[\mathrm{R}]$ poisson.
```
. use https://www.stata-press.com/data/r18/airline
```

(Standard errors scaled using dispersion equal to square root of 1.)
These are precisely the results given in $[R]$ poisson and are those that would have been given had we run glm, family(poisson) link(log). The only minor adjustment we needed to make was to specify the scale(1) option. If scale() is left unspecified, glm assumes scale(1) for discrete distributions and scale(x2) for continuous ones. By default, glm assumes that any user-defined family is continuous because it has no way of checking. Thus, we needed to specify scale(1) because our model is discrete.

Because we were careful in defining the squared deviance, we could have fit this model with IRLS. Because $\log$ is the canonical link for the Poisson family, we would not only get the same regression coefficients but also the same standard errors.

## > Example 6

Suppose now that we wish to use our log link (mylog.ado) with glm's binomial family. This task requires some modification because our current function is not equipped to deal with the binomial denominator, which we are allowed to specify. This denominator is accessible to our link function through the global macro SGLM_m. We now make the modifications and store them in mylog2.ado.

```
program mylog2 // <-- changed
    version 18.0 // (or version 18.5 for StataNow)
    args todo eta mu return
    if 'todo' == -1 {
        global SGLM_lt "My Log, Version 2" // <-- changed
        if "$SGLM_m" == "1" { // <-- changed
            global SGLM_lf "ln(u)" // <-- changed
        } (u)
        else global SGLM_lf "ln(u/$SGLM_m)"
        exit
    }
    if 'todo' == 0 {
        gen double 'eta' = ln('mu'/$SGLM_m) // <-- changed
        exit
    }
    if 'todo' == 1 {
        gen double 'mu' = $SGLM_m*exp('eta') // <-- changed
        exit
    }
    if 'todo' == 2 {
        gen double 'return' = 'mu'
        exit
    }
    if 'todo' == 3 {
        gen double 'return' = 'mu'
        exit
    }
    di as error "Unknown call to glm link function"
    exit 198
end
```

We can now run our new log link with glm's binomial family. Using the flour beetle data from earlier, we have

```
. use https://www.stata-press.com/data/r18/beetle, clear
. glm r ldose, f(bin n) l(mylog2) irls
Iteration 1: Deviance = 2212.108
Iteration 2: Deviance = 452.9352
Iteration 3: Deviance = 429.95
Iteration 4: Deviance = 429.2745
Iteration 5: Deviance = 429.2192
Iteration 6: Deviance = 429.2082
Iteration 7: Deviance = 429.2061
Iteration 8: Deviance = 429.2057
Iteration 9: Deviance = 429.2056
Iteration 10: Deviance = 429.2056
Iteration 11: Deviance = 429.2056
Iteration 12: Deviance = 429.2056
```

```
\begin{tabular}{r|rcrrrr}

\hline
\end{tabular}
```

For a more detailed discussion on user-defined functions, and for an example of a user-defined Newey-West kernel weight, see Hardin and Hilbe (2018).

John Ashworth Nelder (1924-2010) was born in Somerset, England. He studied mathematics and statistics at Cambridge and worked as a statistician at the National Vegetable Research Station and then Rothamsted Experimental Station. In retirement, he was actively affiliated with Imperial College London. Nelder was especially well known for his contributions to the theory of linear models and to statistical computing. He was the principal architect of generalized and hierarchical generalized linear models and of the programs GenStat and GLIM.

Robert William Maclagan Wedderburn (1947-1975) was born in Edinburgh and studied mathematics and statistics at Cambridge. At Rothamsted Experimental Station, he developed the theory of generalized linear models with Nelder and originated the concept of quasilikelihood. He died of anaphylactic shock from an insect bite on a canal holiday.

## Methods and formulas

The canonical reference on GLM is McCullagh and Nelder (1989). The term "generalized linear model" is from Nelder and Wedderburn (1972). Many people use the acronym GLIM for GLM models because of the classic GLM software tool GLIM, by Baker and Nelder (1985). See Dobson and Barnett (2018) for a concise introduction and overview. See Rabe-Hesketh and Everitt (2007) for more examples of GLM using Stata. Hoffmann (2004) focuses on applying generalized linear models, using real-world datasets, along with interpreting computer output, which for the most part is obtained using Stata.

This discussion highlights the details of parameter estimation and predicted statistics. For a more detailed treatment, and for information on variance estimation, see Hardin and Hilbe (2018). glm supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.
glm obtains results by IRLS, as described in McCullagh and Nelder (1989), or by maximum likelihood using Newton-Raphson. The implementation here, however, allows user-specified weights, which we denote as $v_{j}$ for the $j$ th observation. Let $M$ be the number of "observations" ignoring weights. Define

$$
w_{j}= \begin{cases}1 & \text { if no weights are specified } \\ v_{j} & \text { if } \mathrm{f} w e i g h t s \text { or iweights are specified } \\ M v_{j} /\left(\sum_{k} v_{k}\right) & \text { if aweights or pweights are specified }\end{cases}
$$

The number of observations is then $N=\sum_{j} w_{j}$ if fweights are specified and $N=M$ otherwise. Each IRLS step is performed by regress using $w_{j}$ as the weights.
Let $d_{j}^{2}$ denote the squared deviance residual for the $j$ th observation:
For the Gaussian family, $d_{j}^{2}=\left(y_{j}-\widehat{\mu}_{j}\right)^{2}$.
For the Bernoulli family (binomial with denominator 1),

$$
d_{j}^{2}= \begin{cases}-2 \ln \left(1-\widehat{\mu}_{j}\right) & \text { if } y_{j}=0 \\ -2 \ln \left(\widehat{\mu}_{j}\right) & \text { otherwise }\end{cases}
$$

For the binomial family with denominator $m_{j}$,

$$
d_{j}^{2}= \begin{cases}2 y_{j} \ln \left(y_{j} / \widehat{\mu}_{j}\right)+2\left(m_{j}-y_{j}\right) \ln \left\{\left(m_{j}-y_{j}\right) /\left(m_{j}-\widehat{\mu}_{j}\right)\right\} & \text { if } 0<y_{j}<m_{j} \\ 2 m_{j} \ln \left\{m_{j} /\left(m_{j}-\widehat{\mu}_{j}\right)\right\} & \text { if } y_{j}=0 \\ 2 y_{j} \ln \left(y_{j} / \widehat{\mu}_{j}\right) & \text { if } y_{j}=m_{j}\end{cases}
$$

For the Poisson family,

$$
d_{j}^{2}= \begin{cases}2 \widehat{\mu}_{j} & \text { if } y_{j}=0 \\ 2\left\{y_{j} \ln \left(y_{j} / \widehat{\mu}_{j}\right)-\left(y_{j}-\widehat{\mu}_{j}\right)\right\} & \text { otherwise }\end{cases}
$$

For the gamma family, $d_{j}^{2}=-2\left\{\ln \left(y_{j} / \widehat{\mu}_{j}\right)-\left(y_{j}-\widehat{\mu}_{j}\right) / \widehat{\mu}_{j}\right\}$.
For the inverse Gaussian, $d_{j}^{2}=\left(y_{j}-\widehat{\mu}_{j}\right)^{2} /\left(\widehat{\mu}_{j}^{2} y_{j}\right)$.
For the negative binomial,

$$
d_{j}^{2}= \begin{cases}2 \ln \left(1+k \widehat{\mu}_{j}\right) / k & \text { if } y_{j}=0 \\ 2 y_{j} \ln \left(y_{j} / \widehat{\mu}_{j}\right)-2\left\{\left(1+k y_{j}\right) / k\right\} \ln \left\{\left(1+k y_{j}\right) /\left(1+k \widehat{\mu}_{j}\right)\right\} & \text { otherwise }\end{cases}
$$

Let $\phi=1$ if the scale parameter is set to one; otherwise, define $\phi=\widehat{\phi}_{0}(n-k) / n$, where $\widehat{\phi}_{0}$ is the estimated scale parameter and $k$ is the number of covariates in the model (including intercept).

Let $\ln L_{j}$ denote the $\log$ likelihood for the $j$ th observation:
For the Gaussian family,

$$
\ln L_{j}=-\frac{1}{2}\left[\left\{\frac{\left(y_{j}-\widehat{\mu}_{j}\right)^{2}}{\phi}\right\}+\ln (2 \pi \phi)\right]
$$

For the binomial family with denominator $m_{j}$ (Bernoulli if all $m_{j}=1$ ),

$$
\ln L_{j}=\phi \times \begin{cases}\ln \left\{\Gamma\left(m_{j}+1\right)\right\}-\ln \left\{\Gamma\left(y_{j}+1\right)\right\}-\ln \left\{\Gamma\left(m_{j}-y_{j}+1\right)\right\} & \text { if } 0<y_{j}<m_{j} \\ \quad+\left(m_{j}-y_{j}\right) \ln \left(1-\widehat{\mu}_{j} / m_{j}\right)+y_{j} \ln \left(\widehat{\mu}_{j} / m_{j}\right) & \\ m_{j} \ln \left(1-\widehat{\mu}_{j} / m_{j}\right) & \text { if } y_{j}=0 \\ m_{j} \ln \left(\widehat{\mu}_{j} / m_{j}\right) & \text { if } y_{j}=m_{j}\end{cases}
$$

For the Poisson family,

$$
\ln L_{j}=\phi\left[y_{j} \ln \left(\widehat{\mu}_{j}\right)-\widehat{\mu}_{j}-\ln \left\{\Gamma\left(y_{j}+1\right)\right\}\right]
$$

For the gamma family, $\ln L_{j}=-y_{j} / \widehat{\mu}_{j}+\ln \left(1 / \widehat{\mu}_{j}\right)$.
For the inverse Gaussian,

$$
\ln L_{j}=-\frac{1}{2}\left\{\frac{\left(y_{j}-\widehat{\mu}_{j}\right)^{2}}{y_{j} \widehat{\mu}_{j}^{2}}+3 \ln \left(y_{j}\right)+\ln (2 \pi)\right\}
$$

For the negative binomial (let $m=1 / k$ ),

$$
\begin{aligned}
\ln L_{j}= & \phi\left[\ln \left\{\Gamma\left(m+y_{j}\right)\right\}-\ln \left\{\Gamma\left(y_{j}+1\right)\right\}-\ln \{\Gamma(m)\}\right. \\
& \left.-m \ln \left(1+\widehat{\mu}_{j} / m\right)+y_{j} \ln \left\{\widehat{\mu}_{j} /\left(\widehat{\mu}_{j}+m\right)\right\}\right]
\end{aligned}
$$

The overall deviance reported by glm is $D^{2}=\sum_{j} w_{j} d_{j}^{2}$. The dispersion of the deviance is $D^{2}$ divided by the residual degrees of freedom.
The Akaike information criterion (AIC) and Bayesian information criterion (BIC) are given by

$$
\begin{aligned}
& \mathrm{AIC}=\frac{-2 \ln L+2 k}{N} \\
& \mathrm{BIC}=D^{2}-(N-k) \ln (N)
\end{aligned}
$$

where $\ln L=\sum_{j} w_{j} \ln L_{j}$ is the overall $\log$ likelihood.
The Pearson deviance reported by glm is $\sum_{j} w_{j} r_{j}^{2}$. The corresponding Pearson dispersion is the Pearson deviance divided by the residual degrees of freedom. glm also calculates the scaled versions of all of these quantities by dividing by the estimated scale parameter.

## Acknowledgments

glm was written by James Hardin of the Arnold School of Public Health at the University of South Carolina and Joseph Hilbe (1944-2017) of Arizona State University, the coauthors of the Stata Press book Generalized Linear Models and Extensions. The previous version of this routine was written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model. The original version of this routine was published in Royston (1994). Royston's work, in turn, was based on a prior implementation by Joseph Hilbe, first published in Hilbe (1993). Roger Newson wrote an early implementation (Newson 1999) of robust variance estimates for GLM. Parts of this entry are excerpts from Hardin and Hilbe (2018).

## Postestimation commands

The following postestimation commands are available after glm:

| Command | Description |
| :---: | :---: |
| contrast | contrasts and ANOVA-style joint tests of estimates |
| *estat ic | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance-covariance matrix of the estimators (VCE) |
| estat (svy) | postestimation statistics for survey data |
| estimates | cataloging estimation results |
| etable | table of estimation results |
| $\dagger$ forecast | dynamic forecasts and simulations |
| $\dagger$ hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| linktest | link test for model specification |
| * $\dagger$ lrtest | likelihood-ratio test |
| margins | marginal means, predictive margins, marginal effects, and average marginal effects |
| marginsplot | graph the results from margins (profile plots, interaction plots, etc.) |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | predictions, residuals, influence statistics, and other diagnostic measures |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| suest | seemingly unrelated estimation |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

*estat ic and lrtest are not appropriate after glm, irls.
$\dagger_{\text {forecast, hausman, and lrtest }}$ are not appropriate with svy estimation results. forecast is also not appropriate with mi estimation results.

## predict

## Description for predict

predict creates a new variable containing predictions such as expected values, linear predictions, standard errors, residuals, Cook's distance, diagonals of the "hat" matrix, weighted averages, differences between the observed and fitted outcomes, and equation-level scores.

## Menu for predict

Statistics $>$ Postestimation

## Syntax for predict

predict [type] newvar [if] [in] [, statistic options]
statistic Description
Main
mu expected value of $y$; the default
xb linear prediction $\eta=\mathbf{x} \widehat{\boldsymbol{\beta}}$
eta synonym of $x b$
stdp standard error of the linear prediction
anscombe Anscombe (1953) residuals
cooksd
deviance
hat
likelihood
pearson
response
score
working

Cook's distance
deviance residuals
diagonals of the "hat" matrix
a weighted average of standardized deviance and standardized Pearson residuals Pearson residuals
differences between the observed and fitted outcomes
first derivative of the $\log$ likelihood with respect to $\mathbf{x}_{j} \boldsymbol{\beta}$ working residuals

Options
nooffset
adjusted
standardized
studentized
modified
modify calculations to ignore offset variable
adjust deviance residual to speed up convergence
multiply residual by the factor $(1-h)^{-1 / 2}$
multiply residual by one over the square root of the estimated scale parameter modify denominator of residual to be a reasonable estimate of the variance of depvar

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.
$\mathrm{mu}, \mathrm{xb}$, stdp, and score are the only statistics allowed with svy estimation results.

## Options for predict

## Main

mu , the default, specifies that predict calculate the expected value of $y$, equal to $g^{-1}(\mathbf{x} \widehat{\boldsymbol{\beta}})\left[n g^{-1}(\mathbf{x} \widehat{\boldsymbol{\beta}})\right.$ for the binomial family].
xb calculates the linear prediction $\eta=\mathbf{x} \widehat{\boldsymbol{\beta}}$.
eta is a synonym for $x b$.
stdp calculates the standard error of the linear prediction.
anscombe calculates the Anscombe (1953) residuals to produce residuals that closely follow a normal distribution.
cooksd calculates Cook's distance, which measures the aggregate change in the estimated coefficients when each observation is left out of the estimation.
deviance calculates the deviance residuals. Deviance residuals are recommended by McCullagh and Nelder (1989) and by others as having the best properties for examining the goodness of fit of a GLM. They are approximately normally distributed if the model is correct. They may be plotted against the fitted values or against a covariate to inspect the model's fit. Also see the pearson option below.
hat calculates the diagonals of the "hat" matrix, analogous to linear regression.
likelihood calculates a weighted average of standardized deviance and standardized Pearson residuals. pearson calculates the Pearson residuals. Pearson residuals often have markedly skewed distributions for nonnormal family distributions. Also see the deviance option above.
response calculates the differences between the observed and fitted outcomes.
score calculates the equation-level score, $\partial \ln L / \partial\left(\mathbf{x}_{j} \boldsymbol{\beta}\right)$.
working calculates the working residuals, which are response residuals weighted according to the derivative of the link function.

Options
nooffset is relevant only if you specified offset (varname) for glm. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_{j} \mathbf{b}$ rather than as $\mathbf{x}_{j} \mathbf{b}+$ offset $_{j}$.
adjusted adjusts the deviance residual to speed up the convergence to the limiting normal distribution. The adjustment deals with adding to the deviance residual a higher-order term that depends on the variance function family. This option is allowed only when deviance is specified.
standardized requests that the residual be multiplied by the factor $(1-h)^{-1 / 2}$, where $h$ is the diagonal of the hat matrix. This operation is done to account for the correlation between depvar and its predicted value.
studentized requests that the residual be multiplied by one over the square root of the estimated scale parameter.
modified requests that the denominator of the residual be modified to be a reasonable estimate of the variance of depvar. The base residual is multiplied by the factor $(k / w)^{-1 / 2}$, where $k$ is either one or the user-specified dispersion parameter and $w$ is the specified weight (or one if left unspecified).

## margins

## Description for margins

margins estimates margins of response for expected values and linear predictions.

## Menu for margins

Statistics $>$ Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...)...] [options]
```

statistic
Description
mu expected value of $y$; the default
$\mathrm{xb} \quad$ linear prediction $\eta=\mathbf{x} \widehat{\boldsymbol{\beta}}$
eta synonym for $x b$
stdp not allowed with margins
anscombe not allowed with margins
cooksd not allowed with margins
deviance not allowed with margins
hat not allowed with margins
likelihood not allowed with margins
pearson not allowed with margins
response not allowed with margins
score not allowed with margins
working not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

## Remarks and examples

Remarks are presented under the following headings:
Predictions
Other postestimation commands

## Predictions

## > Example 1

After glm estimation, predict may be used to obtain various predictions based on the model. In example 2 of $[\mathrm{R}]$ glm, we mentioned that the complementary $\log -\log$ link seemed to fit the data better than the logit link. Now, we go back and obtain the fitted values and deviance residuals:

```
. use https://www.stata-press.com/data/r18/ldose
. glm r ldose, family(binomial n) link(logit)
(output omitted)
. predict mu_logit
(option mu assumed; predicted mean r)
. predict dr_logit, deviance
. quietly glm r ldose, f(binomial n) l(cloglog)
. predict mu_cl
(option mu assumed; predicted mean r)
. predict dr_cl, d
. format mu_logit dr_logit mu_cl dr_cl %9.5f
. list r mu_logit dr_logit mu_cl dr_cl, sep(4)
```

| $r$ | mu_logit | dr_logit | mu_cl | dr_cl |
| ---: | ---: | ---: | ---: | ---: |
| 6 | 3.45746 | 1.28368 | 5.58945 | 0.18057 |
| 13 | 9.84167 | 1.05969 | 11.28067 | 0.55773 |
| 18 | 22.45139 | -1.19611 | 20.95422 | -0.80330 |
| 28 | 33.89761 | -1.59412 | 30.36942 | -0.63439 |
| 52 | 50.09584 | 0.60614 | 47.77644 | 1.28883 |
| 53 | 53.29092 | -0.12716 | 54.14273 | -0.52366 |
| 61 | 59.22216 | 1.25107 | 61.11331 | -0.11878 |
| 60 | 58.74297 | 1.59398 | 59.94723 | 0.32495 |

In six of the eight cases, $\mid \mathrm{dr} \_$logit $\left|>\left|\mathrm{dr} \_\mathrm{cl}\right|\right.$. The above represents only one of the many available options for predict. See Hardin and Hilbe (2018) for a more in-depth examination.

## Other postestimation commands

- Technical note

After glm estimation, you may perform any of the postestimation commands that you would perform after any other kind of estimation in Stata; see [U] 20 Estimation and postestimation commands. Below, we test the joint significance of all the interaction terms.

```
. use https://www.stata-press.com/data/r18/beetle, clear
. glm r beetle##c.ldose, family(binomial n) link(cloglog)
(output omitted)
. testparm i.beetle beetle#c.ldose
( 1) [r]2.beetle = 0
( 2) [r]3.beetle = 0
( 3) [r]2.beetle#c.ldose = 0
( 4) [r]3.beetle#c.ldose = 0
    chi2( 4) = 249.69
    Prob > chi2 = 0.0000
```

If you wanted to print the variance-covariance matrix of the estimators, you would type estat vce.

If you use the linktest postestimation command, you must also specify the family() and link() options; see [R] linktest.

## Methods and formulas

We follow the terminology used in Methods and formulas of [R] glm.
The deviance residual calculated by predict following glm is $r_{j}^{D}=\operatorname{sign}\left(y_{j}-\widehat{\mu}_{j}\right) \sqrt{d_{j}^{2}}$.
The Pearson residual calculated by predict following glm is

$$
r_{j}^{P}=\frac{y_{j}-\widehat{\mu}_{j}}{\sqrt{V\left(\widehat{\mu}_{j}\right)}}
$$

where $V\left(\widehat{\mu}_{j}\right)$ is the family-specific variance function.

$$
V\left(\widehat{\mu}_{j}\right)= \begin{cases}\widehat{\mu}_{j}\left(1-\widehat{\mu}_{j} / m_{j}\right) & \text { if binomial or Bernoulli }\left(m_{j}=1\right) \\ \widehat{\mu}_{j}^{2} & \text { if gamma } \\ 1 & \text { if Gaussian } \\ \widehat{\mu}_{j}^{3} & \text { if inverse Gaussian } \\ \widehat{\mu}_{j}+k \widehat{\mu}_{j}^{2} & \text { if negative binomial } \\ \widehat{\mu}_{j} & \text { if Poisson }\end{cases}
$$

The response residuals are given by $r_{j}^{R}=y_{j}-\widehat{\mu}_{j}$. The working residuals are

$$
r_{j}^{W}=\left(y_{j}-\widehat{\mu}_{j}\right)\left(\frac{\partial \eta}{\partial \mu}\right)_{j}
$$

and the score residuals are

$$
r_{j}^{S}=\frac{y_{j}-\widehat{\mu}_{j}}{V\left(\widehat{\mu}_{j}\right)}\left(\frac{\partial \eta}{\partial \mu}\right)_{j}^{-1}
$$

Define $\widehat{W}=V(\widehat{\mu})$ and $X$ to be the covariate matrix. $h_{j}$, then, is the $j$ th diagonal of the hat matrix given by

$$
\widehat{H}=\widehat{W}^{1 / 2} X\left(X^{T} \widehat{W} X\right)^{-1} X^{T} \widehat{W}^{1 / 2}
$$

As a result, the likelihood residuals are given by

$$
r_{j}^{L}=\operatorname{sign}\left(y_{j}-\widehat{\mu}_{j}\right)\left\{h_{j}\left(r_{j}^{P \prime}\right)^{2}+\left(1-h_{j}\right)\left(r_{j}^{D \prime}\right)^{2}\right\}^{1 / 2}
$$

where $r_{j}^{P \prime}$ and $r_{j}^{D \prime}$ are the standardized Pearson and standardized deviance residuals, respectively. By standardized, we mean that the residual is divided by $\left\{1-h_{j}\right\}^{1 / 2}$.

Cook's distance is an overall measure of the change in the regression coefficients caused by omitting the $i$ th observation from the analysis. Computationally, Cook's distance is obtained as

$$
C_{j}=\frac{\left(r_{j}^{P \prime}\right)^{2} h_{j}}{k\left(1-h_{j}\right)}
$$

where $k$ is the number of regressors, including the constant.
Anscombe residuals are given by

$$
r_{j}^{A}=\frac{A\left(y_{j}\right)-A\left(\widehat{\mu}_{j}\right)}{A^{\prime}\left(\widehat{\mu}_{j}\right)\left\{V\left(\widehat{\mu}_{j}\right)\right\}^{1 / 2}}
$$

where

$$
A(\cdot)=\int \frac{d \mu}{V^{1 / 3}(\mu)}
$$

Deviance residuals may be adjusted (predict, adjusted) to make the following correction:

$$
r_{j}^{D a}=r_{j}^{D}+\frac{1}{6} \rho_{3}(\theta)
$$

where $\rho_{3}(\theta)$ is a family-specific correction. See Hardin and Hilbe (2018) for the exact forms of $\rho_{3}(\theta)$ for each family.

Syntax
Methods and formulas

## Description

gmm performs generalized method of moments (GMM) estimation. With the interactive version of the command, you enter the residual equation for each moment condition directly into the dialog box or on the command line by using substitutable expressions. The moment-evaluator program version gives you greater flexibility in exchange for increased complexity; with this version, you write a program in an ado-file that calculates the moments based on a vector of parameters passed to it.
gmm can fit both single- and multiple-equation models. It allows moment conditions of the form $E\left\{\mathbf{z}_{i} u_{i}(\beta)\right\}=\mathbf{0}$, where $\mathbf{z}_{i}$ is a vector of instruments, and $u_{i}(\boldsymbol{\beta})$ is an error term, as well as more general moment conditions of the form $E\left\{\mathbf{h}_{i}\left(\mathbf{z}_{i} ; \boldsymbol{\beta}\right)\right\}=\mathbf{0}$. gmm works with cross-sectional, time-series, and longitudinal (panel) data.

[^30]$\operatorname{rexp}_{j}$ and $\operatorname{dexp}_{j k}$ may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.
bootstrap, by, collect, jackknife, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see $[R]$ bootstrap.
aweights are not allowed with the jackknife prefix; see $[R]$ jackknife.
aweights, fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
$\operatorname{rexp}_{j}$ and $\operatorname{dexp}_{j k}$ are substitutable expressions, that is, Stata expressions that also contain parameters to be estimated. The parameters are enclosed in curly braces and must satisfy the naming requirements for variables; \{beta\} is an example of a parameter. The notation \{lcname:varlist\} is allowed for linear combinations of multiple covariates and their parameters. For example, $\{x b$ : mpg price turn _cons\} defines a linear combination of the variables mpg, price, turn, and _cons (the constant term). See Substitutable expressions under Remarks and examples below.

## Options

## Model

derivative ( $[$ reqname $\mid \#] /$ name $=\operatorname{dexp}_{j k}$ ) specifies the derivative of residual equation reqname or \# with respect to parameter name. If reqname or \# is not specified, gmm assumes that the derivative applies to the first residual equation.
For a moment condition of the form $E\left\{\mathbf{z}_{j i} u_{j i}(\boldsymbol{\beta})\right\}=\mathbf{0}$, derivative $\left(j / \beta_{k}=\operatorname{dexp}{ }_{j k}\right)$ is to contain a substitutable expression for $\partial u_{j i} / \partial \beta_{k}$. If you specified m as the reqname, then for a moment condition of the form $E\left\{\mathbf{z}_{m i} u_{m i}(\boldsymbol{\beta})\right\}=\mathbf{0}$, you can specify derivative ( $\mathrm{m} / \beta_{k}=$ $\operatorname{dexp}_{m k}$ ), where $m$ is the index of $m$.
$\operatorname{dexp}_{j k}$ uses the same substitutable expression syntax as is used to specify residual equations. If you declare a linear combination in a residual equation, you provide the derivative for the linear combination; gmm then applies the chain rule for you. See Specifying derivatives under Remarks and examples below for examples.
If you do not specify the derivative() option, gmm calculates derivatives numerically. You must either specify no derivatives or specify a derivative for each of the $k$ parameters that appears in each of the $j$ residual equations unless the derivative is identically zero. You cannot specify some analytic derivatives and have gmm compute the rest numerically.
twostep, onestep, and igmm specify which estimator is to be used. You can specify at most one of these options. twostep is the default.
twostep requests the two-step GMM estimator. gmm obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, and then reestimates the parameters based on that weight matrix.
onestep requests the one-step GMM estimator. The parameters are estimated based on an initial weight matrix, and no updating of the weight matrix is performed except when calculating the appropriate variance-covariance (VCE) matrix.
igmm requests the iterative GMM estimator. gmm obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, reestimates the parameters based on that weight matrix, computes a new weight matrix, and so on, to convergence. Convergence is declared when the relative change in the parameter vector is less than igmmeps(), the relative change in the weight matrix is less than igmmweps(), or igmmiterate() iterations have been
completed. Hall (2005, sec. 2.4 and 3.6) mentions that there may be gains to finite-sample efficiency from using the iterative estimator.
variables (varlist) specifies the variables in the model. gmm ignores observations for which any of these variables has a missing value. If you do not specify variables (), then gmm assumes all the observations are valid and issues an error message if any residual equations evaluate to missing for any observations at the initial value of the parameter vector.
nocommonesample requests that gmm not restrict the estimation sample to be the same for all equations. By default, gmm will restrict the estimation sample to observations that are available for all equations in the model, mirroring the behavior of other multiple-equation estimators such as nlsur, sureg, or reg3. For certain models, however, different equations can have different numbers of observations. For these models, you should specify nocommonesample. See Dynamic panel-data models below for one application of this option. You cannot specify weights if you specify nocommonesample.

Instruments
instruments ([reqlist: $]$ varlist $[$, noconstant $]$ ) specifies a list of instrumental variables to be used. If you specify a single residual equation, then you do not need to specify the equations to which the instruments apply; you can omit the reqlist and simply specify instruments (varlist). By default, a constant term is included in varlist; to omit the constant term, use the noconstant suboption: instruments(varlist, noconstant).

If your model has multiple moment conditions of the form

$$
E\left\{\begin{array}{c}
\mathbf{z}_{1 i} u_{1 i}(\boldsymbol{\beta}) \\
\cdots \\
\mathbf{z}_{q i} u_{q i}(\boldsymbol{\beta})
\end{array}\right\}=\mathbf{0}
$$

then you can specify multiple corresponding residual equations. Then, specify the reqname or an reqlist to indicate the residual equations for which the list of variables is to be used as instruments if you do not want that list applied to all the residual equations. For example, you might type

```
gmm (main: rexp 1) (rexp 2) (rexp ), instruments(z1 z2) ///
    instruments(2: z3) instruments(main 3: z4)
```

Variables $z 1$ and $z 2$ will be used as instruments for all three equations, $z 3$ will be used as an instrument for the second equation, and $z 4$ will be used as an instrument for the first and third equations. Notice that we chose to supply a name for the first residual equation but not the second two, identifying each by its equation number.
varlist may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists, respectively.
xtinstruments ([reqlist: $]$ varlist, lags $\left(\#_{1} / \#_{2}\right)$ ) is for use with panel-data models in which the set of available instruments depends on the time period. As with instruments(), you can prefix the list of variables with residual equation names or numbers to target instruments to specific equations. Unlike with instruments(), a constant term is not included in varlist. You must xtset your data before using this option; see [XT] xtset.
If you specify
gmm ..., xtinstruments( $\mathrm{x}, \operatorname{lags}(1 /).) \ldots$
then for panel $i$ and period $t$, gmm uses $x_{i, t-1}, x_{i, t-2}, \ldots, x_{i 1}$ as instruments. More generally, specifying xtinstruments ( $\mathrm{x}, \operatorname{lags}\left(\#_{1}, \#_{2}\right)$ ) uses $x_{i, t-\#_{1}}, \ldots, x_{i, t-\#_{2}}$ as instruments; setting $\#_{2}=$. requests all available lags. $\#_{1}$ and $\#_{2}$ must be zero or positive integers.
gmm automatically excludes observations for which no valid instruments are available. It does, however, include observations for which only a subset of the lags is available. For example, if you request that lags one through three be used, then gmm will include the observations for the second and third time periods even though fewer than three lags are available as instruments.

## Weight matrix

wmatrix (wmtype [, independent]) specifies the type of weight matrix to be used in conjunction with the two-step and iterated GMM estimators.
Specifying wmatrix (robust) requests a weight matrix that is appropriate when the errors are independent but not necessarily identically distributed. wmatrix (robust) is the default.

Specifying wmatrix(cluster clustvar) requests a weight matrix that accounts for arbitrary correlation among observations within clusters identified by clustvar.

Specifying wmatrix(hac kernel \#) requests a heteroskedasticity- and autocorrelation-consistent (HAC) weight matrix using the specified kernel (see below) with \# lags. The bandwidth of a kernel is equal to the number of lags plus one.

Specifying wmatrix (hac kernel opt [\#]) requests an HAC weight matrix using the specified kernel, and the lag order is selected using Newey and West's (1994) optimal lag-selection algorithm. \# is an optional tuning parameter that affects the lag order selected; see the discussion in Methods and formulas.

Specifying wmatrix (hac kernel) requests an HAC weight matrix using the specified kernel and $N-2$ lags, where $N$ is the sample size.

There are three kernels available for HAC weight matrices, and you can request each one by using the name used by statisticians or the name perhaps more familiar to economists:
bartlett or nwest requests the Bartlett (Newey-West) kernel;
parzen or gallant requests the Parzen (Gallant) kernel; and
quadraticspectral or andrews requests the quadratic spectral (Andrews) kernel.
Specifying wmatrix (unadjusted) requests a weight matrix that is suitable when the errors are homoskedastic. In some applications, the GMM estimator so constructed is known as the (nonlinear) two-stage least-squares (2SLS) estimator.

Including the independent suboption creates a weight matrix that assumes moment conditions are independent. This suboption is often used to replicate other models that can be motivated outside the GMM framework, such as the estimation of a system of equations by system-wide 2SLS. This suboption has no effect if only one residual equation is specified.
wmatrix() has no effect if onestep is also specified.
center requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.
winitial (iwtype [, independent]) specifies the weight matrix to use to obtain the first-step parameter estimates.

Specifying winitial (unadjusted) requests a weight matrix that assumes the moment conditions are independent and identically distributed. This matrix is of the form $\left(\mathbf{Z}^{\prime} \mathbf{Z}\right)^{-1}$, where $\mathbf{Z}$ represents all the instruments specified in the instruments () option. To avoid a singular weight matrix, you should specify at least $q-1$ moment conditions of the form $E\left\{\mathbf{z}_{h i} u_{h i}(\boldsymbol{\beta})\right\}=\mathbf{0}$, where $q$ is the number of moment conditions, or you should specify the independent suboption.

Including the independent suboption creates a weight matrix that assumes moment conditions are independent. Elements of the weight matrix corresponding to covariances between two moment conditions are set equal to zero. This suboption has no effect if only one residual equation is specified.
winitial(unadjusted) is the default.
winitial (identity) requests that the identity matrix be used.
winitial (xt xtspec) is for use with dynamic panel-data models in which one of the residual equations is specified in first-differences form. xtspec is a string consisting of the letters "L" and "D", the length of which is equal to the number of residual equations in the model. You specify "L" for a residual equation if that residual equation is written in levels, and you specify "D" for a residual equation if it is written in first differences; xtspec is not case sensitive. When you specify this option, you can specify at most one residual equation in levels and one residual equation in first differences. See the examples listed in Dynamic panel-data models under Remarks and examples below.
winitial (matname) requests that Stata matrix matname be used. You cannot specify the independent suboption if you specify winitial(matname).

## SE/Robust

vce (vcetype [, independent]) specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
vce (unadjusted) specifies that an unadjusted (nonrobust) VCE matrix be used; this, along with the twostep option, results in the "optimal two-step GMM" estimates often discussed in textbooks.
The default vcetype is based on the wmtype specified in the wmatrix() option. If wmatrix () is specified but vce() is not, then vcetype is set equal to wmtype. To override this behavior and obtain an unadjusted (nonrobust) VCE matrix, specify vce(unadjusted).

Specifying vce(bootstrap) or vce(jackknife) results in standard errors based on the bootstrap or jackknife, respectively. See $[R]$ vec_option, $[R]$ bootstrap, and $[R]$ jackknife for more information on these VCEs.

The syntax for vcetypes other than bootstrap and jackknife is identical to those for wmatrix(). quickderivatives requests that an alternative method be used to compute the numerical derivatives for the VCE. This option has no effect if you specify the derivatives(), hasderivatives, or haslfderivatives option.

The VCE depends on a matrix of partial derivatives that gmm must compute numerically unless you supply analytic derivatives. This Jacobian matrix will be especially large if your model has many instruments, residual equations, or parameters.
By default, gmm computes each element of the Jacobian matrix individually, searching for an optimal step size each time. Although this procedure results in accurate derivatives, it is computationally taxing: gmm may have to evaluate the moments of your model five or more times for each element of the Jacobian matrix.

When you specify the quickderivatives option, gmm computes all derivatives corresponding to a parameter at once, using a fixed step size proportional to the parameter's value. This method requires just two evaluations of the model's moments to compute an entire column of the Jacobian matrix and therefore has the most impact when you specify many instruments or residual equations.

Most of the time, the two methods produce virtually identical results, but the quickderivatives method may fail if a residual equation is highly nonlinear or if instruments differ by orders of magnitude. In the rare case where you specify quickderivatives and obtain suspiciously large or small standard errors, try refitting your model without this option.

## Reporting

level (\#); see [R] Estimation options.
title(string) specifies an optional title that will be displayed just above the table of parameter estimates.
title2 (string) specifies an optional subtitle that will be displayed between the title specified in title() and the table of parameter estimates. If title2() is specified but title() is not, title2() has the same effect as title().
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(\#), fvwrapon(style), cformat (\%fmt), pformat (\%fmt), sformat (\% fint), and nolstretch; see [R] Estimation options.
$\sqrt{\text { Optimization }}$
from(initial_values) specifies the initial values to begin the estimation. You can specify a parameter name, its initial value, another parameter name, its initial value, and so on, or you can specify a $1 \times k$ matrix, where $k$ is the number of parameters in the model. For example, to initialize alpha to 1.23 and delta to 4.57 , you would type
gmm ..., from(alpha 1.23 delta 4.57) ...
or equivalently

```
matrix define initval = (1.23, 4.57)
gmm ..., from(initval) ...
```

Initial values declared in the from() option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, gmm exits with an error message. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model.
igmmiterate(\#), igmmeps(\#), and igmmweps(\#) control the iterative process for the iterative GMM estimator. These options can be specified only if you also specify igmm.
igmmiterate(\#) specifies the maximum number of iterations to perform with the iterative GMM estimator. The default is the number set using set maxiter, which is 300 by default.
igmmeps (\#) specifies the convergence criterion used for successive parameter estimates when the iterative GMM estimator is used. The default is igmmeps ( $1 \mathrm{e}-6$ ). Convergence is declared when the relative difference between successive parameter estimates is less than igmmeps () and the relative difference between successive estimates of the weight matrix is less than igmmweps().
igmmweps (\#) specifies the convergence criterion used for successive estimates of the weight matrix when the iterative GMM estimator is used. The default is igmmweps ( $1 \mathrm{e}-6$ ). Convergence is declared when the relative difference between successive parameter estimates is less than igmmeps () and the relative difference between successive estimates of the weight matrix is less than igmmweps ().
optimization_options: technique(), conv_maxiter(), conv_ptol(), conv_vtol(),
conv_nrtol(), tracelevel(). technique() specifies the optimization technique to use; gn
(the default), nr , dfp , and bfgs are allowed. conv_maxiter() specifies the maximum number
of iterations; conv_ptol(), conv_vtol(), and conv_nrtol() specify the convergence criteria for the parameters, gradient, and scaled Hessian, respectively. tracelevel () allows you to obtain additional details during the iterative process. See [M-5] optimize().

The following options pertain only to the moment-evaluator program version of gmm.
$\qquad$ Model
evaluator_options refer to any options allowed by your moment_prog.
hasderivatives and haslfderivatives indicate that you have written your moment-evaluator program to compute derivatives. You may specify one or the other but not both. If you do not specify either of these options, gmm computes the derivatives numerically.
hasderivatives indicates that your moment-evaluator program computes parameter-level derivatives.
haslfderivatives indicates that your moment-evaluator program computes equation-level derivatives and is useful only when you specify the parameters of your model using the \{lcname: varlist $\}$ syntax of the parameters () option.
See Details of moment-evaluator programs below for more information.
equations (namelist) specifies the names of the residual equations in the model. If you specify both equations() and nequations(), the number of names in the former must match the number specified in the latter.
nequations(\#) specifies the number of residual equations in the model. If you do not specify names with the equations() option, gmm numbers the residual equations $1,2,3, \ldots$. If you specify both equations() and nequations(), the number of names in the former must match the number specified in the latter.
parameters (namelist) specifies the names of the parameters in the model. The names of the parameters must comply with the naming conventions of Stata's variables; see [U] 11.3 Naming conventions.

Alternatively, you can use parameter equation notation to specify linear combinations of parameters. Each linear combination is of the form \{lcname:varlist\}, where varlist is one or more variable names. Specify the system variable _cons in varlist to include a constant term. Distinguish between \{lcname: varlist\}, in which lcname identifies the linear combination, and (reqname:rexp), in which reqname identifies the residual equation. When you use linear-combination syntax, gmm prepends each element of the parameter vector passed to your evaluator program with lcname: to generate unique names.

If you specify both parameters() and nparameters(), the number of names in the former must match the number specified in the latter.
nparameters (\#) specifies the number of parameters in the model. If you do not specify names with the parameters() option, gmm names them b1, b2, ..., b\#. If you specify both parameters() and nparameters(), the number of names in the former must match the number specified in the latter.

The following option is available with gmm but is not shown in the dialog box:
coeflegend; see [R] Estimation options.

## Remarks and examples

Introduction<br>Substitutable expressions<br>The weight matrix and two-step estimation<br>Obtaining standard errors<br>Factor-variable coefficients in multiple residual functions<br>Parameter interpretation using margins<br>Exponential (Poisson) regression models<br>Specifying derivatives<br>Exponential regression models with panel data<br>Rational-expectations models<br>System estimators<br>Dynamic panel-data models<br>Details of moment-evaluator programs

## Introduction

The GMM estimator is a workhorse of modern econometrics and is discussed in all the leading textbooks, including Cameron and Trivedi (2005, 2022), Davidson and MacKinnon (1993), Greene (2018, 500-534), Ruud (2000), Hayashi (2000), Wooldridge (2010), Hamilton (1994), and Baum (2006). An excellent treatise on GMM with a focus on time-series applications is Hall (2005). The collection of papers by Mátyás (1999) provides both theoretical and applied aspects of GMM. Here we give a brief introduction to the methodology and emphasize how the various options of gmm are used.

The starting point for the GMM estimator is the analogy principle, which says we can estimate a parameter by replacing a population moment condition with its sample analogue. For example, the mean of an independent and identically distributed (i.i.d.) population is defined as the value $\mu$ such that the first (central) population moment is zero; that is, $\mu$ solves $E(y-\mu)=0$, where $y$ is a random draw from the population. The analogy principle tells us that to obtain an estimate, $\widehat{\mu}$, of $\mu$, we replace the population-expectations operator with its sample analogue (Manski 1988; Wooldridge 2010),

$$
E(y-\mu)=0 \longrightarrow \frac{1}{N} \sum_{i=1}^{N}\left(y_{i}-\widehat{\mu}\right)=0 \longrightarrow \widehat{\mu}=\frac{1}{N} \sum_{i=1}^{N} y_{i}
$$

where $N$ denotes sample size, and $y_{i}$ represents the $i$ th observation of $y$ in our dataset. The estimator $\widehat{\mu}$ is known as the method of moments (MM) estimator because we started with a population moment condition and then applied the analogy principle to obtain an estimator that depends on the observed data.

Ordinary least-squares (OLS) regression can also be viewed as an MM estimator. In the model

$$
y=\mathbf{x}^{\prime} \boldsymbol{\beta}+u
$$

we assume that $u$ has mean zero conditional on $\mathbf{x}: E(u \mid \mathbf{x})=0$. This conditional expectation implies the unconditional expectation $E(\mathbf{x} u)=\mathbf{0}$ because, with the law of iterated expectations,

$$
E(\mathbf{x} u)=E_{\mathbf{x}}\{E(\mathbf{x} u \mid \mathbf{x})\}=E_{\mathbf{x}}\{\mathbf{x} E(u \mid \mathbf{x})\}=\mathbf{0}
$$

(Using the law of iterated expectations to derive unconditional expectations based on conditional expectations, perhaps motivated by subject theory, is extremely common in GMM estimation.) Continuing, we see that

$$
E(\mathbf{x} u)=E\left\{\mathbf{x}\left(y-\mathbf{x}^{\prime} \boldsymbol{\beta}\right)\right\}=\mathbf{0}
$$

Applying the analogy principle, we obtain

$$
E\left\{\mathbf{x}\left(y-\mathbf{x}^{\prime} \beta\right)\right\} \longrightarrow \frac{1}{N} \sum_{i=1}^{N} \mathbf{x}_{i}\left(y_{i}-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}\right)=\mathbf{0}
$$

so that

$$
\widehat{\boldsymbol{\beta}}=\left(\sum_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right)^{-1} \sum_{i} \mathbf{x}_{i} y_{i}
$$

which is just the more familiar formula $\widehat{\boldsymbol{\beta}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}$ written with summation notation.
In both of the previous examples, the number of parameters we were estimating equaled the number of moment conditions. In the first example, we estimated one parameter, $\mu$, and had one moment condition $E(y-\mu)=0$. In the second example, the parameter vector $\boldsymbol{\beta}$ had $k$ elements, as did the vector of regressors $\mathbf{x}$, yielding $k$ moment conditions. Ignoring peculiar cases, we see that a model of $m$ equations in $m$ unknowns has a unique solution; and because the residual equations in these examples were linear, we could solve for the parameters analytically. If the moment conditions had been nonlinear, we would have had to use numerical techniques to solve for the parameters, but that is not a significant limitation with modern computers.

What if we have more moment conditions than parameters? Say we have $q$ moment conditions and $k$ parameters. A model of $q>k$ equations in $k$ unknowns does not have a unique solution. Any size- $k$ subset of the moment conditions would yield a consistent parameter estimate, though the parameter estimate would in general be different depending on which $k$ moment conditions we used.

For concreteness, let's return to our regression model,

$$
y=\mathbf{x}^{\prime} \boldsymbol{\beta}+u
$$

Now, however, we no longer wish to assume that $E(\mathbf{x} u)=\mathbf{0}$; we suspect that the error term $u$ affects one or more elements of $\mathbf{x}$. Thus, we can no longer use the OLS estimator. Suppose we have a vector $\mathbf{z}$ with the properties that $E(\mathbf{z} u)=\mathbf{0}$, that the rank of $E\left(\mathbf{z}^{\prime} \mathbf{z}\right)$ equals $q$, and that the rank of $E\left(\mathbf{z}^{\prime} \mathbf{x}\right)=k$. The first assumption simply states that $\mathbf{z}$ is not correlated with the error term. The second assumption rules out perfect collinearity among the elements of $\mathbf{z}$. The third assumption, known as the rank condition in econometrics, ensures that $\mathbf{z}$ is sufficiently correlated with $\mathbf{x}$ and that the estimator is feasible. If some elements of $\mathbf{x}$ are not correlated with $u$, then they should also appear in $\mathbf{z}$.

If $q<k$, then the rank of $E\left(\mathbf{z}^{\prime} \mathbf{x}\right)<k$, which violates the rank condition.
If $q=k$, then we can use the simpler MM estimator we already discussed; we would obtain what is sometimes called the simple instrumental-variables estimator $\widehat{\boldsymbol{\beta}}=\left(\sum_{i} \mathbf{z}_{i} \mathbf{x}_{i}^{\prime}\right)^{-1} \sum_{i} \mathbf{z}_{i} y_{i}$. The rank condition ensures that $\sum_{i} \mathbf{z}_{i} \mathbf{x}_{i}^{\prime}$ is invertible, at least in the population.

If $q>k$, the GMM estimator chooses the value, $\widehat{\boldsymbol{\beta}}$, that minimizes a quadratic function of the moment conditions. We could define

$$
\widehat{\boldsymbol{\beta}} \equiv \arg \min _{\boldsymbol{\beta}}\left\{\frac{1}{N} \sum_{i} \mathbf{z}_{i} u_{i}(\boldsymbol{\beta})\right\}^{\prime}\left\{\frac{1}{N} \sum_{i} \mathbf{z}_{i} u_{i}(\boldsymbol{\beta})\right\}
$$

where for our linear regression example $u_{i}(\boldsymbol{\beta})=y_{i}-\mathbf{x}_{i}^{\prime} \boldsymbol{\beta}$. This estimator tries to make the moment conditions as close to zero as possible. This simple estimator, however, applies equal weight to each of the moment conditions; and as we will see later, we can obtain more efficient estimators by choosing to weight some moment conditions more highly than others.

Consider the quadratic function

$$
Q(\boldsymbol{\beta})=\left\{\frac{1}{N} \sum_{i} \mathbf{z}_{i} u_{i}(\boldsymbol{\beta})\right\}^{\prime} \mathbf{W}\left\{\frac{1}{N} \sum_{i} \mathbf{z}_{i} u_{i}(\boldsymbol{\beta})\right\}
$$

where $\mathbf{W}$ is a symmetric positive-definite matrix known as a weight matrix. Then we define the GMM estimator as

$$
\begin{equation*}
\widehat{\boldsymbol{\beta}} \equiv \arg \min _{\boldsymbol{\beta}} Q(\boldsymbol{\beta}) \tag{1}
\end{equation*}
$$

Continuing with our regression model example, if we choose

$$
\mathbf{W}=\left(\frac{1}{N} \sum_{i} \mathbf{z}_{i} \mathbf{z}_{i}^{\prime}\right)^{-1}
$$

then we obtain

$$
\begin{gathered}
\widehat{\boldsymbol{\beta}}=\left\{\left(\frac{1}{N} \sum_{i} \mathbf{x}_{i} \mathbf{z}_{i}^{\prime}\right)\left(\frac{1}{N} \sum_{i} \mathbf{z}_{i} \mathbf{z}_{i}^{\prime}\right)^{-1}\left(\frac{1}{N} \sum_{i} \mathbf{z}_{i} \mathbf{x}_{i}^{\prime}\right)\right\}^{-1} \times \\
\\
\left(\frac{1}{N} \sum_{i} \mathbf{x}_{i} \mathbf{z}_{i}^{\prime}\right)\left(\frac{1}{N} \sum_{i} \mathbf{z}_{i} \mathbf{z}_{i}^{\prime}\right)^{-1}\left(\frac{1}{N} \sum_{i} \mathbf{z}_{i} y_{i}\right)
\end{gathered}
$$

which is the well-known two-stage least-squares (2SLS) estimator. Our choice of weight matrix here was based on the assumption that $u$ was homoskedastic. A feature of GMM estimation is that by selecting different weight matrices, we can obtain estimators that can tolerate heteroskedasticity, clustering, autocorrelation, and other features of $u$. See [R] ivregress for more information about the 2SLS and linear GMM estimators.

Returning to the case where the model is "just identified", meaning that $q=k$, if we apply the GMM estimator, we will obtain the same estimate, $\widehat{\boldsymbol{\beta}}$, regardless of our choice of $\mathbf{W}$. Because $q=k$, if a unique solution exists, it will set all the sample moment conditions jointly to zero, so $\mathbf{W}$ has no impact on the value of $\boldsymbol{\beta}$ that minimizes the objective function.

We will highlight other features of the GMM estimator and the gmm command as we proceed through examples. First, though, we discuss how to specify moment conditions by using substitutable expressions.

## Substitutable expressions

To use the interactive version of gmm, you define the moment conditions by using substitutable expressions. Your moment conditions are of the form $E\left\{z_{i}^{\prime} u_{i}(\boldsymbol{\beta})\right\}=\mathbf{0}$, where $u_{i}(\boldsymbol{\beta})$ is a residual expression that depends on the parameter vector $\boldsymbol{\beta}$ as well as variables in your dataset, though we suppress expressing the variables for notational simplicity.
gmm requires you to write a substitutable expression for $u_{i}(\boldsymbol{\beta})$. This substitutable expression is the right-hand side of the model written in terms of $u$, or in the language of Stata syntax, a "residual equation". For example, suppose you want to fit the function $y=f(\mathbf{x} ; \boldsymbol{\beta})+u$. In this example, $u_{i}(\boldsymbol{\beta})=u=y-f(\mathbf{x} ; \boldsymbol{\beta})$, so you would type
gmm (y - expression for $f(\mathbf{x} ; \boldsymbol{\beta})), \ldots$
Note that we are not restricted to models with additive error terms.

In general, there are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in curly braces: \{b0\}, \{param\}, etc. Parameter names must follow the same conventions as variable names. See [U] 11.3 Naming conventions.
2. Initial values for parameters are given by including an equal sign and the initial value inside the curly braces: $\{b 0=1\}$, $\{$ param $=3.571\}$, etc.
You can also specify initial values by using the from() option. Initial values specified in from () override whatever initial values are given within the substitutable expression. If you do not specify an initial value for a parameter, it is initialized to 0 .
3. Linear combinations of variables can be included using the notation \{lcname: varlist $\}$ : $\{\mathrm{xb}$ : mpg price weight\}, \{score: wxz\}, etc. Parameters of linear combinations are initialized to 0 .

Substitutable expressions may use any mathematical expression involving scalars and variables. See [U] 13.2 Operators and [U] 13.3 Functions for more information on expressions.

The notation $\{\mathrm{xb}: \mathrm{x} 1 \mathrm{x} 2 \mathrm{x} 3\}$ tells gmm that you want a linear combination of the variables x 1 , x 2 , and x 3 . We named this linear combination xb , so gmm will name the three parameters $\mathrm{xb}: \mathrm{x} 1$, $\mathrm{xb}: \mathrm{x} 2$, and $\mathrm{xb}: \mathrm{x} 3$, which corresponds to the three variables x 1 , x 2 , and x 3 in the xb equation. Specify _cons to include a constant term in a linear combination. Factor variables and time-series operators are allowed; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

Once we have declared the variables in the linear combination xb , we can refer to the linear combination in our substitutable expression by using the notation xb :. The colon is not optional; it tells gmm that you are referring to a previously declared linear combination, not an individual parameter. This shorthand notation is also handy when specifying derivatives, as we will show later.
> Example 1: OLS regression
In Introduction, we stated that OLS is an MM estimator. Say that we want to fit the model

$$
\mathrm{mpg}=\beta_{0}+\beta_{1} \text { weight }+\beta_{2} \text { length }+u
$$

where $u$ is an i.i.d. error term. Recall that the moment condition for ols regression is $E(\mathbf{x} u)=\mathbf{0}$, where $\mathbf{x}$, the list of instruments, is the same as the list of regressors in the model. Writing this in the form required for a gmm substitutable expression, we have

$$
u=\mathrm{mpg}-\beta_{0}-\beta_{1} \text { weight }-\beta_{2} \text { length }
$$

The right-hand side of the equation is the substitutable expression that we will provide to gmm. We give $\beta_{0}, \beta_{1}$, and $\beta_{2}$ the parameter names b 0 , b 1 , and b 2 and enclose them in curly braces. Because linear combinations declared in substitutable expressions do not include a constant term by default, we include our own (b0). We specify the regressors, weight and length, with their respective parameters and also in the instruments() option. gmm includes a constant term in the instrument list by default, so we do not need to add an additional term there. Thus, our command is

| (1978 automob <br> - gmm (mpg - | e data) <br> 1\}*weight | $\{b 2\} * \text { lengt }$ | $-\{b 0\})$ | instruments (weight length) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Step 1 |  |  |  |  |  |  |

Instruments for equation 1: weight length _cons
Because the number of moments equals the number of parameters we are estimating, the model is said to be "just identified" or "exactly identified". Therefore, the choice of weight matrix has no impact on the solution to (1), and the criterion function $Q(\boldsymbol{\beta})$ achieves its minimum value at 0 .

The OLS estimator is a one-step GMM estimator, but we did not bother to specify the onestep option, because the model is just identified. Doing a second step of GMM estimation affects neither the point estimates nor the standard errors, so to keep the syntax as simple as possible, we did not include the onestep option. The first step of estimation resulted in $Q(\boldsymbol{\beta})=0$ as expected, and the second step of estimation did not change the minimized value of $Q(\boldsymbol{\beta})$. (The final iterations of the first and second steps result in $Q(\boldsymbol{\beta})$ values of 0 for all practical purposes.)

When you do not specify either the wmatrix () or the vce() option, gmm reports heteroskedasticityrobust standard errors. The parameter estimates reported here match those that we would obtain from the command

```
. regress mpg weight length, vce(robust)
```

The standard errors reported by that regress command would be larger than those reported by gmm by a factor of $\operatorname{sqrt}(74 / 71)$ because regress makes a small-sample adjustment to the estimated variance matrix while gmm does not. Likewise, if we had specified the vce (unadjusted) option with our gmm command, then our standard errors would differ by a factor of $\operatorname{sqrt}(74 / 71)$ from those reported by regress without the vce(robust) option.

We could have submitted our substitutable expression using the notation for linear combinations of parameters. If we select $x b$ as the name of our parameter equation, we could type

```
. gmm (mpg - {xb: weight length _cons}), instruments(weight length)
```

and obtain identical results. With this syntax, instead of having parameters b1, b2, and b0, we would have parameters xb :weight, xb :length, and xb :_cons. Note that _cons allows you to include a constant in a linear combination, so this time, we do not have to specify a separate parameter from our varlist.

Factor variables and time-series-operated variables are allowed in the linear combinations. For example,

```
. regress mpg i.foreign i.foreign#c.weight, vce(robust)
```

produces the same results as

```
. gmm (mpg - {xb:i.foreign i.foreign#c.weight _cons}),
> instruments(i.foreign i.foreign#c.weight)
```

See [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists for an introduction to factor variables and time-series operators. See example 4 for an example of factor-variable syntax with gmm. See example 15 for an example using time-series-operated variables.

## > Example 2: Instrumental-variables regression

In Introduction, we mentioned that 2SLS can be viewed as a GMM estimator. In example 1 of $[R]$ ivregress, we fit by a 2SLS model of rental rates (rent) as a function of the value of owner-occupied housing (hsngval) and the percentage of the population living in urban areas (pcturban):

$$
\text { rent }=\beta_{0}+\beta_{1} \text { hsngval }+\beta_{2} \text { pcturban }+u
$$

We argued that random shocks that affect rental rates likely also affect housing values, so we treated hsngval as an endogenous variable. As additional instruments, we used family income, faminc, and three regional dummies (reg2-reg4).

To replicate the results of ivregress 2sls by using gmm, we type

| $\begin{aligned} & \text { ( use https://www.stata-press.com/data/r18/] } \\ & \text { (1980 Census housing data) } \\ & \text {. gmm (rent - \{xb:hsngval pcturban _cons\}), } \end{aligned}$ |  |  |  |  |  |  |

Instruments for equation 1: pcturban faminc reg2 reg3 reg4 _cons
We specified vce(unadjusted) so that we would obtain an unadjusted VCE matrix and our standard errors would match those reported in [R] ivregress.

Note how we specified the instruments() option. In Introduction, we mentioned that the moment conditions for the 2SLS estimator are $E(\mathbf{z} u)=\mathbf{0}$, and we mentioned that if some elements of $\mathbf{x}$ (the regressors) are not endogenous, then they should also appear in $\mathbf{z}$. In this model, we assume the regressor pcturban is exogenous, so we included it in the list of instrumental variables. Commands like ivregress, ivprobit, and ivtobit accept standard varlists, so they can deduce the exogenous regressors in the model. Because gmm accepts arbitrary functions in the form of substitutable expressions, it has no way of discerning the exogenous variables of the model on its own.

Also notice that we specified the onestep option. The 2SLS estimator is a one-step GMM estimator that is based on a weight matrix that assumes the error terms are i.i.d. Unlike the previous example, this example had more instruments than parameters, so the minimized value of $Q(\boldsymbol{\beta})$ is nonzero. We discuss the weight matrix and its relationship to two-step estimation next.

## The weight matrix and two-step estimation

Recall our definition of the GMM estimator given in (1). The estimator, $\widehat{\boldsymbol{\beta}}$, depends on the choice of the weight matrix, $\mathbf{W}$. Under relatively mild assumptions, our estimator, $\widehat{\boldsymbol{\beta}}$, is consistent regardless of the choice of $\mathbf{W}$, so how are we to decide what $\mathbf{W}$ to use? The most common solution is to use the two-step estimator, which we now describe.

A key result in Hansen's (1982) seminal paper is that if we denote by $\mathbf{S}$ the covariance matrix of the moment conditions, then the optimal (in a way we make precise later) GMM estimator is the one that uses a weight matrix equal to the inverse of the moment covariance matrix. That is, if we let $\mathbf{S}=\operatorname{Cov}(\mathbf{z} u)$, then we want to use $\mathbf{W}=\mathbf{S}^{-1}$. But how do we obtain $\mathbf{S}$ in the first place?

If we assume that the errors are i.i.d., then

$$
\operatorname{Cov}(\mathbf{z} u)=E\left(u^{2} \mathbf{z} \mathbf{z}^{\prime}\right)=\sigma^{2} E\left(\mathbf{z z}^{\prime}\right)
$$

where $\sigma^{2}$ is the variance of $u$. Because $\sigma^{2}$ is a positive scalar, we can ignore it when solving (1). Thus, we compute

$$
\begin{equation*}
\widehat{\mathbf{W}}_{1}=\left(\frac{1}{N} \sum_{i} \mathbf{z}_{i} \mathbf{z}_{i}^{\prime}\right)^{-1} \tag{2}
\end{equation*}
$$

which does not depend on any unknown model parameters. (Notice that $\widehat{\mathbf{W}}_{1}$ is the same weight matrix used in 2SLS.) Given $\widehat{\mathbf{W}}_{1}$, we can solve (1) to obtain an initial estimate, say, $\widehat{\boldsymbol{\beta}}_{1}$.

Our estimate, $\widehat{\boldsymbol{\beta}}_{1}$, is consistent, so by Slutsky's theorem, the sample residuals $\widehat{u}$ computed at this value of $\boldsymbol{\beta}$ will also be consistent. Using virtually the same arguments used to justify the Huber/Eicker/White heteroskedasticity-robust VCE, if we assume that the residuals are independent though not identically distributed, we can estimate $\mathbf{S}$ as

$$
\widehat{\mathbf{S}}=\frac{1}{N} \sum_{i} \widehat{u}_{i}^{2} \mathbf{z}_{i} \mathbf{z}_{i}^{\prime}
$$

Then, in the second step, we re-solve (1), using $\widehat{\mathbf{W}}_{2}=\widehat{\mathbf{S}}^{-1}$, which yields the two-step GMM estimate $\widehat{\beta}_{2}$. If the residuals exhibit clustering, you can specify wmatrix (cluster varname) so that gmm computes a weight matrix that does not assume the $u_{i}$ 's are independent within clusters identified by varname. You can specify wmatrix (hac ...) to obtain weight matrices that are suitable for when the $u_{i}$ 's exhibit autocorrelation as well as heteroskedasticity.

We could take the point estimates from the second round of estimation and use them to compute yet another weight matrix, $\widehat{\mathbf{W}}_{3}$, say, re-solve (1) yet again, and so on, stopping when the parameters or weight matrix do not change much from one iteration to the next. This procedure is known as the iterative GMM estimator and is obtained with the igmm option. Asymptotically, the two-step and iterative GMM estimators have the same distribution. However, Hall (2005, 90) suggests that the iterative estimator may have better finite-sample properties.

Instead of computing $\widehat{\mathbf{W}}_{1}$ as in (2), we could simply choose $\widehat{\mathbf{W}}_{1}=\mathbf{I}$, the identity matrix. The initial estimate, $\widehat{\boldsymbol{\beta}}_{1}$, would still be consistent. You can request this behavior by specifying the winitial (identity) option. However, if you specify all of your moment conditions of the form $E(\mathbf{z} u)=\mathbf{0}$, we recommend using the default winitial (unadjusted) instead; the rescaling of the moment conditions implied by using a homoskedastic initial weight matrix makes the numerical routines used to solve (1) more stable.

If you fit a model with more than one of the moment conditions of the form $E\{h(\mathbf{z} ; \boldsymbol{\beta})\}=\mathbf{0}$, then you must use winitial(identity) or winitial (unadjusted, independent). With moment conditions of that form, you do not specify a list of instruments, and gmm cannot evaluate (2)-the matrix expression in parentheses would necessarily be singular, so it cannot be inverted.

## > Example 3: Two-step linear GMM estimator

From the previous discussion and the comments in Introduction, we see that the linear 2SLS estimator is a one-step GMM estimator where we use the weight matrix defined in (2) that assumes the errors are i.i.d. If we use the 2SLS estimate of $\boldsymbol{\beta}$ to obtain the sample residuals, compute a new weight matrix based on those residuals, and then do a second step of GMM estimation, we obtain the linear two-step GMM estimator as implemented by ivregress gmm.

In example 3 of $[R]$ ivregress, we fit the model of rental rates as discussed in example 2 above. We now allow the residuals to be heteroskedastic, though we will maintain our assumption that they are independent. We type

```
. gmm (rent - {xb:hsngval pcturban _cons}), instruments(pcturban faminc reg2-reg4)
Step 1
Iteration 0: GMM criterion Q(b) = 56115.03
Iteration 1: GMM criterion Q(b) = 110.91583
Iteration 2: GMM criterion Q(b) = 110.91583
Step 2
Iteration 0: GMM criterion Q(b) = . }240608
Iteration 1: GMM criterion Q(b) = . }1367280
Iteration 2: GMM criterion Q(b) = . }1367280
GMM estimation
Number of parameters = 3
Number of moments = 6
Initial weight matrix: Unadjusted Number of obs = 50
GMM weight matrix: Robust
```

|  | Robust |  |  |  |  |  |
| ---: | ---: | :---: | :---: | :---: | :---: | ---: |
|  | Coefficient | std. err. | $z$ | $\mathrm{P}>\|\mathrm{z}\|$ | [95\% conf. interval] |  |
| hsngval | .0014643 | .0004473 | 3.27 | 0.001 | .0005877 | .002341 |
| pcturban | .7615482 | .2895105 | 2.63 | 0.009 | .1941181 | 1.328978 |
| _cons | 112.1227 | 10.80234 | 10.38 | 0.000 | 90.95052 | 133.2949 |

Instruments for equation 1: pcturban faminc reg2 reg3 reg4 _cons
By default, gmm computes a heteroskedasticity-robust weight matrix before the second step of estimation, though we could have specified wmatrix (robust) if we wanted to be explicit. Because we did not specify the vce() option, gmm used a heteroskedasticity-robust one. Our results match those in example 3 of $[R]$ ivregress. Moreover, the only substantive difference between this example and example 2 is that here we did not specify the onestep option, so we obtain the two-step estimates.

## Obtaining standard errors

This section is a bit more theoretical and can be skipped on first reading. However, the information is sufficiently important that you should return to this section at some point.

So far in our discussion, we have focused on point estimation without much mention of how we obtain the standard errors of the estimates. We also mentioned that if we choose $\mathbf{W}$ to be the inverse of the covariance matrix of the moment conditions, then we obtain the "optimal" GMM estimator. We elaborate those points now.

Using mostly standard statistical arguments, we can show that for the GMM estimator defined in (1), the variance of $\widehat{\boldsymbol{\beta}}$ is given by

$$
\begin{equation*}
\operatorname{Var}(\widehat{\boldsymbol{\beta}})=\frac{1}{N}\left\{\overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})^{\prime} \mathbf{W} \overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})\right\}^{-1} \overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})^{\prime} \mathbf{W} \mathbf{S W} \overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})\left\{\overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})^{\prime} \mathbf{W} \overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})\right\}^{-1} \tag{3}
\end{equation*}
$$

where

$$
\overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})=\left.\frac{1}{N} \sum_{i} \mathbf{z}_{i} \frac{\partial u_{i}}{\partial \boldsymbol{\beta}}\right|_{\boldsymbol{\beta}=\widehat{\boldsymbol{\beta}}} \quad \text { or } \quad \overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})=\left.\frac{1}{N} \sum_{i} \frac{\partial \mathbf{h}_{i}}{\partial \boldsymbol{\beta}}\right|_{\boldsymbol{\beta}=\widehat{\boldsymbol{\beta}}}
$$

as the case may be and $\mathbf{S}=E\left(\mathbf{z} u u^{\prime} \mathbf{z}^{\prime}\right)$.
Assuming the vce (unadjusted) option is not specified, gmm reports standard errors based on the robust variance matrix defined in (3). For the two-step estimator, $\mathbf{W}$ is the weight matrix requested with the wmatrix() option, and it is calculated based on the residuals obtained after the first estimation step. The second-step point estimates and residuals are obtained, and $\mathbf{S}$ is calculated based on the specification of the vce() option. For the iterated estimator, $\mathbf{W}$ is calculated based on the second-to-last round of estimation, while $\mathbf{S}$ is based on the residuals obtained after the last round of estimation. Computation of the covariance matrix for the one-step estimator is, perhaps surprisingly, more involved; we discuss the covariance matrix with the one-step estimator in the technical note at the end of this section.

If the model is exactly identified, the matrix $\overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})$ is square, and (3) simplifies to the following:

$$
\operatorname{Var}(\widehat{\boldsymbol{\beta}})=\frac{1}{N} \overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})^{-1} \mathbf{S}\left(\overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})^{\prime}\right)^{-1}
$$

If we choose the weight matrix to be the inverse of the covariance matrix of the moment conditions so that $\mathbf{W}=\mathbf{S}^{-1}$, then (3) simplifies substantially:

$$
\begin{equation*}
\operatorname{Var}(\widehat{\boldsymbol{\beta}})=\frac{1}{N}\left\{\overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})^{\prime} \mathbf{W} \overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})\right\}^{-1} \tag{4}
\end{equation*}
$$

The GMM estimator constructed using this choice of weight matrix along with the covariance matrix in (4) is known as the "optimal" GMM estimator. One can show that if in fact $\mathbf{W}=\mathbf{S}^{-1}$, then the variance in (4) is smaller than the variance in (3) of any other GMM estimator based on the same moment conditions but with a different choice of weight matrix. Thus, the optimal GMM estimator is also known as the efficient GMM estimator because it has the smallest variance of any estimator based on the given moment conditions.

To obtain standard errors from gmm based on the optimal GMM estimator, you specify the vce (unadjusted) option. We call that VCE unadjusted because we do not recompute the residuals after estimation to obtain the matrix $\mathbf{S}$ required in (3) or allow for the fact that those residuals may not be i.i.d. Some statistical packages by default report standard errors based on (4) and offer standard errors based on (3) only as an option or not at all. While the optimal GMM estimator is theoretically appealing, Cameron and Trivedi $(2005,177)$ suggest that in finite samples, it need not perform better than the GMM estimator that uses (3) to obtain standard errors.

## - Technical note

Computing the covariance matrix of the parameters after using the one-step estimator is actually a bit more complex than after using the two-step or iterative estimator. We can illustrate most of the intricacies by using linear regression with moment conditions of the form $E\left\{\mathbf{x}\left(y-\mathbf{x}^{\prime} \boldsymbol{\beta}\right)\right\}=\mathbf{0}$.

If you specify winitial (unadjusted) and vce(unadjusted), then the initial weight matrix will be computed as

$$
\begin{equation*}
\widehat{\mathbf{W}}_{1}=\left(\frac{1}{N} \sum_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right)^{-1} \tag{5}
\end{equation*}
$$

Moreover, for linear regression, we can show that

$$
\overline{\mathbf{G}}(\widehat{\boldsymbol{\beta}})=\frac{1}{N} \sum_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}
$$

so that (4) becomes

$$
\begin{align*}
\operatorname{Var}(\widehat{\boldsymbol{\beta}}) & =\frac{1}{N}\left\{\left(\frac{1}{N} \sum_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right)\left(\frac{1}{N} \sum_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right)^{-1}\left(\frac{1}{N} \sum_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right)\right\}^{-1} \\
& =\left(\sum_{i} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right)^{-1} \\
& =\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \tag{6}
\end{align*}
$$

However, we know that the nonrobust covariance matrix for the OLS estimator is actually $\widehat{\sigma}^{2}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1}$. What is missing from (6) is the scalar $\widehat{\sigma}^{2}$, the estimated variance of the residuals. When you use the one-step estimator and specify winitial (unadjusted), the weight matrix (5) does not include the $\widehat{\sigma}^{2}$ term because gmm does not have a consistent estimate of $\boldsymbol{\beta}$ from which it can then estimate $\sigma^{2}$. The point estimates are still correct because multiplying the weight matrix by a scalar factor does not affect the solution to the minimization problem.

To circumvent this issue, if you specify winitial (unadjusted) and vce(unadjusted), gmm uses the estimated $\widehat{\boldsymbol{\beta}}$ (which is consistent) to obtain a new unadjusted weight matrix that does include the term $\widehat{\sigma}^{2}$ so that evaluating (4) will yield correct standard errors.

If you use the two-step or iterated GMM estimator, this extra effort is not needed to obtain standard errors because the first-step (and subsequent steps') estimate of $\boldsymbol{\beta}$ is consistent and can be used to estimate $\sigma^{2}$ or some other weight matrix based on the wmatrix() option. Straightforward algebra shows that this extra effort is also not needed if you request any type of adjusted (robust) covariance matrix with the one-step estimator.

A similar issue arises when you specify winitial (identity) and vce(unadjusted) with the one-step estimator. Again the solution is to compute an unadjusted weight matrix after obtaining $\widehat{\beta}$ so that (4) provides the correct standard errors.

We have illustrated the problem and solution using a single-equation linear model. However, the problem arises whenever you use the one-step estimator with an unadjusted VCE, regardless of the number of equations, and gmm handles all the details automatically. Computation of Hansen's $J$ statistic presents an identical issue, and gmm takes care of that as well.
